Quick Start Guide

1 Quick Start Guide

1.1 Features

RoboTask can easily automate any series of tasks on your computer system, whether you are a novice or advanced user. You don't even have to know how to program—use RoboTask to build your own automated solutions quickly and easily. Yet RoboTask is powerful.

For example, RoboTask can help you avoid losing important data when you create a backup task for placing files on a remote server.

The software can manage and trigger a wide variety of repetitive tasks to save your valuable time. With RoboTask, you don't need complicated batch files or scripts.

Here are many examples of what RoboTask can do for you:

- Runs applications and open documents.
- Manages automatic backups.
- Alerts you of any changes in your folders.
- Shuts down Windows and powers off your computer triggered by any event you choose.
- Processes files and folders (copies, moves, renames, deletes).
- Works with FTP and Web servers (downloads, uploads, etc).
- Sends letters and files by e-mail.
- Starts and stops Windows NT services.
- Sends network messages as WinPopups.
- Acts as an alarm clock.
- Much more!

RoboTask can be used for an unlimited number of tasks. When creating a task, you decide what the task needs to do and when. Every task has two parts:

1. Actions
2. Triggering events

Actions

First, you must decide what actions you want to accomplish. You can select built-in actions in RoboTask to accomplish the following:

- Run applications.
- Open or print documents.
- Emulate your keystrokes.
- File and folder processing (copy, move, delete, rename, synchronize folders).
- Work with FTP servers (download, upload, rename, delete).
- Work with e-mail (check for e-mail, send e-mail).
- Work with ZIP files (pack files, extract files).
- Work with windows (focus, maximize, minimize, restore, close, hide, unhide).
- Flow control (if-then, file loop, text loop, dataset loop, and so forth).

Triggering events

A triggering event can be one of the following:

- A specific time

- When something happens on your computer.

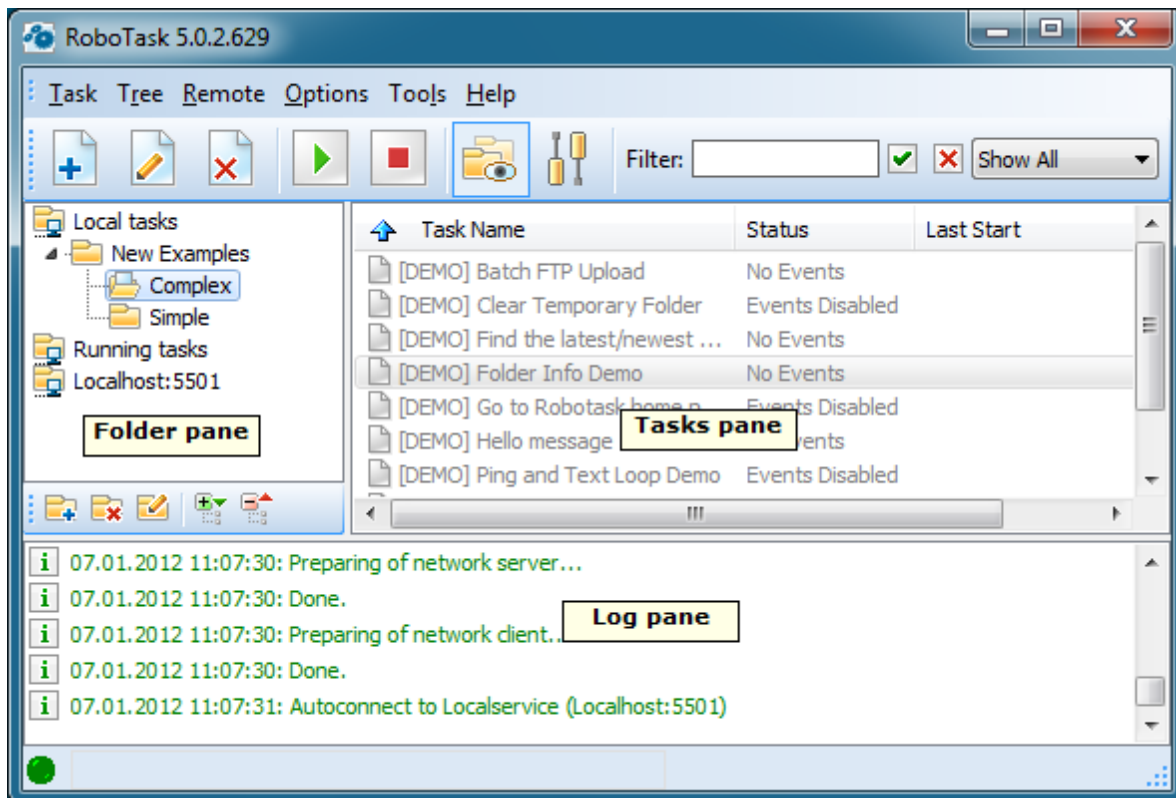

Practically anything that happens on your computer can trigger RoboTask to perform an action. An example would be when RoboTask automatically updates a log and uploads it to a website whenever you receive an email with a subject that is a particular string of words or contains a word such as "Important".

The following are examples of triggering events:

- Scheduler (at a specified time).
- Hot Keys (when a special key is pressed).
- Tray Icon (when you double-click it).
- File Monitor (when a particular file is created, destroyed, changed, renamed).
- Dial-up Connection Monitor (when a connection is made or broken).
- Window Watcher (when a window is created, activated, closed, and so forth).
- System Events (time, spooler, device, display changed, log on, log off, on idle).

1.2 Getting Started in the RoboTask Window

The following information introduces you to the RoboTask main window.

Folder Pane

Displays a tree of the task folders. This is useful for organizing your tasks.

Task pane

Task Name Column

Displays the name of the task.

Status Column

Displays whether the task is enabled or disabled. You must run the task manually if the task is disabled by double-clicking it. You can change the status of a task: select the task and right-click.

Log Pane

Displays the log messages when you open RoboTask or when a task runs. You can set options for the log when you add a task or edit one on the Advanced tab of the Add Task dialog box.

**New Task**

Allows you to add a new task. You can select actions and triggering events.

Edit Task

Allows you to modify a task. You can edit the settings for actions and triggering events.

Delete Task

Removes the task that you select in the main window.

Run Task

Starts the task that you select in the main window.

Stop Task

Stops the task that you select in the main window.

Show/Hide Task Tree

Displays or hides the task tree at the left of the main window.

Settings

Allows you to set preferences for RoboTask.

**New Folder**

Allows you to create a new folder and enter the name.

Remove Folder

Removes the task folder that you select.

Rename Folder

Allows you to rename the selected task folder.

Expand All

Hides the folders in the tree and displays only the top level folder.

Expand All

Displays all the folders in the tree.

Shortcut Menus

If you select a task in the **Task Name** column and right-click, the following commands appear on the shortcut menu:

- **Enabled** - Allows the task to start automatically when a triggering event in the task occurs.
- **New** - Creates a new task.
- **Edit** - Modifies the task that you select.
- **Delete** - Removes a task.
- **Run** - Starts a task.
- **Stop** - Ends a task.
- **Duplicate** - Copies a task. This is useful if you want to create a new task quickly and then modify it.
- **Create Shortcut** - Adds a shortcut to the task on your desktop. This is useful if you want to quickly start a task without opening RoboTask.

If you point to the Log pane and right-click, the following commands appear on the shortcut menu:

- **Clear Log** - Removes all messages from the Log pane.
- **Copy Selected to Clipboard** - Copies the lines that you have selected in the Log pane and places them on the Windows Clipboard.
- **Select All** - Selects all the lines in the Log pane so that you can quickly copy them.

1.3 Create Tasks

1. Click [Task > New](#)^[43].
2. On the **Actions** tab, click the **Add** button.
3. Select an action. Some of the actions require additional settings. A dialog box appears with specific settings that you can select.
4. After entering the settings, click the **Triggering Events** tab.
5. Click the **Add** button.
6. Select a triggering event. Some of the triggering events require additional settings. A dialog box appears with specific settings that you can select.
7. After entering the settings for the triggering event, click OK.
8. To run your task, click the **Run Selected Task** button in the main window.

Tip

Some actions or triggering events do not have specific settings that you can enter.

1.4 Run Tasks

1. In the right pane of the RoboTask window, select a task.
2. Click **Task > Run** or press CTRL + ENTER on the keyboard

3. In the right pane of the RoboTask window, the status column displays the results of running the task.

Tip

- You can run a task without opening RoboTask. Select a task in the RoboTask window and click **Task > Create Shortcut on Desktop**. This adds a shortcut to that task on your desktop. You can double-click the task to start it.

1.5 Edit Tasks

1. In the RoboTask window, select a task.
2. Click **Task > Edit**.
3. On the **Edit Task** dialog box, select the options that you want.

Tip

- To remove a task from the list in the RoboTask window, select a task and click **Task > Delete**.

1.6 Customize RoboTask

1. Click **Options > Settings**.
2. On the **Preferences** dialog box, set the options you want.

1.7 Purchasing

Click **Help > Purchase**. Also you may purchase full version of RoboTask from [official web site](#).

1.8 License Agreement

The RoboTask is distributed as try-before-you-buy. This means:

1. All copyrights to **RoboTask** are exclusively owned by the author - NeoWise Software.
2. Anyone may use this software during an evaluation period of 30 days. Following this evaluation period of 30 days or less, if you wish to continue to use **RoboTask**, you must purchase it.
3. Once purchased, the user is granted a non-exclusive license to use **RoboTask** on one computer (i.e. a single CPU), for any legal purpose, at a time:
 - **Personal license** entitles you to use RoboTask only on a single computer at home for

personal purposes.

- **Business license** entitles you to use RoboTask on server or workstation by employees of your company or organization at single location.
 - If you need to use RoboTask on a few computers (servers or workstations) you must purchase corresponding amount of licenses.
4. Registered user is granted free upgrades of **RoboTask** within one year period since purchasing of RoboTask. In order to prolong the period of free upgrades, user must purchase new registration code with discount.
 5. The licensed **RoboTask** software may not be rented or leased, but may be permanently transferred, if the person receiving it agrees to terms of this license. If the software is an update, the transfer must include the update and all previous versions.
 6. The trial version of **RoboTask** may be freely distributed, provided the distribution package is not modified. No person or company may charge a fee for the distribution trial version of RoboTask without written permission from the copyright holder.
 7. **RoboTask** IS DISTRIBUTED "AS IS". NO WARRANTY OF ANY KIND IS EXPRESSED OR IMPLIED. YOU USE AT YOUR OWN RISK. THE AUTHOR WILL NOT BE LIABLE FOR DATA LOSS, DAMAGES, LOSS OF PROFITS OR ANY OTHER KIND OF LOSS WHILE USING OR MISUSING THIS SOFTWARE.
 8. You may not use, copy, emulate, clone, rent, lease, sell, modify, decompile, disassemble, otherwise reverse engineer, or transfer the licensed program, or any subset of the licensed program, except as provided for in this agreement. Any such unauthorized use shall result in immediate and automatic termination of this license and may result in criminal and/or civil prosecution. All rights not expressly granted here are reserved by NeoWise Software.
 9. Installing and using **RoboTask** signifies acceptance of these terms and conditions of the license.
 10. If you do not agree with the terms of this license you must remove **RoboTask** files from your storage devices and cease to use the product.

Thank you for using the original RoboTask.

Part

Several practical recommendations

2 Several practical recommendations

2.1 Using Variables in Tasks

2.1.1 Usage of Variables

For building complex automation schemes, RoboTask provides two types of variables that you can use in actions and triggering events:

- System variables that are pre-defined.
- User variables that you can define yourself.

When you insert a variable name as a parameter or part of a parameter in an action or triggering event, the variable content is processed, instead of the variable name.

For example, if you want to show a message containing the day of the week, you should use the `{DayOfWeek}` variable.

When you run the task that contains the `{DayOfWeek}` variable, the variable is replaced by the name of current week day. If you insert this variable in a Show Message action that includes the message defined as "Today `{DayOfWeek}`!", when you run this task on Wednesday, the following message displays: "Today Wednesday!".

You can use as many variables as you need in an event or action. Any time that you define the same parameter many times, you should use a variable. This allows you to change the variable in one place and all your tasks that contain the variable update automatically.

The Usage of variable names in actions.

Beginning with the version of *RoboTask 5.3* all the actions where variables are assigned allow to use other variables in the variable name. That can be useful, for example, when creating enumerated variables like these:

```
Line1  
Line2  
...  
Line10
```

In this case it is possible to specify a variable name like `Line{num}`, where *num* contains the ordinal iteration number of a cycle. Thereby, it is possible to create pseudo array.

However, it is strongly recommended not to abuse that feature. Although such approach provides more flexibility, it is easy to get confused in variables names. Therefore we advise to specify the variables names explicitly, if it is possible to avoid dynamic names.

Variables that Contain Other Variables

You can even use variables within other variables; this is useful if you want to specify a value of a variable for other variables. For example, you can define a variable with a name `{Yesterday}`. `{Yesterday}` contains another variable with a value `{MonthIncDays(-1)}/{IncDays(-1)}/{YearIncDays(-1)}`. When you use the `{Yesterday}` variable, it returns yesterday's date.

Arrays

To make your tasks even more powerful, you can use variables as arrays. This means you can specify more than one values separated with commas. To access the first value, use index 0: `{MyVar(0)}`. To access the second value, use index 1: `{MyVar(1)}`. And so on.

For example, if to add a variable with name `{MyArray}` and value *One, Two, Three*, you can use that variable as shown below:

- `{MyArray}` = One, Two, Three
- `{MyArray(0)}` = One
- `{MyArray(1)}` = Two
- `{MyArray(2)}` = Three

Another example:

- `{MyArray}` = "First item", "Second item", "Third item"
- `{MyArray(0)}` = First item
- `{MyArray(1)}` = Second item
- `{MyArray(2)}` = Third item

2.1.2 System variables

You can view [system variables](#)^[367] in the RoboTask variables dialog box (*the Options | Variables menu*). The list is divided into categories. Each variable in the list has a brief description. Thus, it will not be difficult to study [the set of variables](#)^[367] and we will not describe them here. There are more than 80 system variables available now. Actually they are functions that are executed at the moment of line generation.

Some variables require a parameter, for example:

`ExtractFileNameNoExt()`

You should specify the full name of the file as the parameter of this variable. For example:

`{ExtractFileNameNoExt(C:\Folder\File.ext)}`

It is possible to use embedded variables. Suppose we have a custom variable named *MyFileName* containing the name of a file. To extract the file name without its extension, type:

`{ExtractFileNameNoExt({MyFileName})}`

In this case, RoboTask will find `{MyFileName}` first and then use the found string as a parameter.

This rule applies to all system variables that require a parameter.

2.1.3 Custom variables

RoboTask allows you to save intermediate data in users variables. There is also a whole set of actions that cannot work without user variables. For instance, loops. While using variables, you should remember about some peculiarities.

User variables are global for all tasks

It means that one and the same variable is visible, can be used and can be modified in any task. On the one hand, it is very convenient: data can be passed from one task to another. But on the other hand, if you have two tasks running simultaneously, they use one and the same variable and it is done unintentionally, you may get a completely unexpected result.

Tip

If you use variables that are not supposed to be used in other tasks, use special prefixes of this task in the names of these variables.

For example:

TSK1_Counter, TSK1_CurrentFile, etc.

Also you may simply declare necessary variables as local. See [Local variables](#) topic

RoboTask saves user variables for future sessions

Variables you create in tasks are stored until you remove them using the «RoboTask variables» form (Options | Variables) or the «Remove Variable» action inside the task. When you exit RoboTask, variables save their values for future sessions.

As a rule, variables make sense only for the task they are created in and after using RoboTask for a while, you may get a rather long list of user variables that you do not need anymore.

Tip

Insert actions removing unnecessary variables at the end of tasks.

2.1.4 Local Variables

What local variables are

Local variables of a task are custom variables that "live" only while the task is running.

- Differences between local and global variables:
- Local variables "live" only while their task is running. Unlike local variables, global variables live starting from RoboTask startup (or since such a variable is created) and until RoboTask is exited or until such a variable is deleted.
- The values of local variables are not preserved till the next session of working with RoboTask.
- Local variables can be edited and accessed only within the running task. Global variables can be accessed and edited in any task.

They are similar to global variables in all other aspects.

Advantages of using local variables:

We do not have to take care of deleting unnecessary variables when the task is complete because local variables are deleted from memory automatically when their task is complete.

When you use local variables, you do not have to worry that they will be changed by another task. And vice versa: the use of local variables guarantees that the values of variables will be

—preserved while the task is running.

If several tasks that can change one and the same variable are running simultaneously, the result may be unpredictable. Suppose we have two similar tasks that go through files in a loop, but they do it in different folders. Both tasks assign the name of the current file to the **CurrentFile** variable. If these tasks are running simultaneously, we may end up with quite a few problems. It is easy to avoid it if you declare the **CurrentFile** variable as local in both tasks.

Such a situation is not a rare one, especially if you have several hundreds of tasks. You can also create new tasks by copying an existing one and changing a few steps in it.

How to declare local variables

You can declare local variables on the ["Local variables" tab](#)^[47] of the task editor. There are two ways to declare them:

Enumerate the names of the variables;

Assign initial values to them.

If you enumerate them, just fill the list of names for local variables: one variables per line. For example, like this:

```
LineCount
FileToUpload
CurrentFile
```

etc.

To assign an initial value, specify this value after the "=" character. For example, like this

```
LineCount = 0
FileToUpload = c:\incoming\list.txt
CurrentFile = note.txt
```

etc.

You can assign initial values not to all variables. By default, local variables contain an empty value (an empty string).

By default, the list of local variables is empty. It means that all variables that are used in a task will be processed as global ones when you run the task.

How to use local variables

There are no additional requirements regarding the use of local variables. The same tools are used to work with local variables as with global ones:

Actions from the Variables group

[Create variable](#)^[175]

[Set Variable](#)^[177]

[Remove variable](#)^[178]

[Increment variable](#)^[178]

[Delimit Variable](#)^[179]

Inserting variables into strings in various actions.

For example:

```
Current folder is "{CurrentFolder}"
```

Using the methods of the [RoboTaskApp](#)^[36] object: **ExpandText**, **SetUserVariable**, etc.

The rules according to which RoboTask processes local variables are very simple:

Once a variable is called, RoboTask first tries to find it among the local variables of the task.

Calling a variable means any call: assigning a new value or calculating the variable's value when macro insertions with the help of variables are substituted.

If the local variable is declared, further operations (reading or assigning the value) will be applied to the local variable. Otherwise, RoboTask will process the variable as a global one.

Thus, if we declare a local variable that has the same name as a global variable, the local variable will completely override the global variable. The running task will not simply see the global variable.

It is better to declare all internal variables as local ones for most tasks. As a rule, these variables are used in a loop or to pass data from one step in the task to another. When you use local variables, you need not worry that the new task will mess up data from other tasks. And vice versa – that some other task running simultaneously changes the data of the current task. On the other hand, if you need to pass some data to another task, you should make sure that the necessary variables are absent in the list of local variables.

2.1.5 Create a Variable

1. To define a variable, click **Options > Variables**.
2. On the **User Variables** tab, click the **Add** button.
3. On the **User Variable** dialog box, enter the name of the variable in the **Variable Name** box.
4. Enter the values in the **Initial Values** box.

Tip

In the **Initial Value** edit box, you can also type the names of other variables to define a variable.

2.1.6 Add Variables to a Task

You can add variables to an action or triggering event contained in a task.

1. When you create a task, on the **Edit Task** dialog box, select an action or triggering event.
2. When you do this, some actions or triggering events display a dialog box in which you can enter specific settings for the action or event. On this dialog box, select a field and click the **{V}** button.
3. On the **RoboTask Variables** dialog box, select a variable in the list and click the **Select** button.
4. The variable appears in the field that you selected on the dialog box for the action or triggering event.

2.1.7 Saving of a result into a variable

During their operation almost all actions of the RoboTask demand that their results should be assigned into user variables. In this case it is necessary to specify the variable name.

A variable name is some string composed of Latin letters (ASCII symbols) and numbers without any spaces.

It is better to specify the variable name explicitly, that is without curly brackets.

But composing of a variable name using other variables is permitted. In this case variables should be separated with curly brackets like when composing any expression in the RoboTask.

What happens if you use curly brackets in a variable name?

- The RoboTask tries to compute the values of expressions in curly brackets (expand variables) and substitute the value into the expression.
- Then, the got expression is checked whether it is correspond to the rules of variable names.
- If the got name is correct, the RoboTask assigns the necessary value into a variable with this name.

2.1.8 Rules for using variables in expressions

Using variables in actions permits to achieve more flexibility of an algorithm. Sometimes you just can't do without using variables. For example, in cycles.

If you use expressions with variables in parameters of actions, RoboTask at first expands all variables, and only after that uses the result for the action. In other words, RoboTask computes the variable value and substitutes the value for the variable in the expression.

For example, the expression

```
Temporary file is {UniqueFileName({TempDir}\*.tmp)}
```

will approximately have the following form after its computation:

```
Temporary file is C:\Users\User1\AppData\Local\Temp\DA0PUY08.tmp
```

The rules for computing values are simple:

- **The rule of visibility.** At first, RoboTask tries to find the variable in the list of local variables. Then, if it fails, it looks up among global ones. If the variable isn't found, substitution doesn't occur. System variables are always global. Inherently they are functions which return the result of some computations. This rule is described in the unit "Local Variables".
- **The depth of expanding variable.** If variables are used in an expression by means of braces **{}**, the variables are expanded to the whole depth. That is, firstly the value of variable is computed, and then the result is expanded if it contains variables. And so on, to the end. However, sometimes it is necessary to expand only the specified variable without further recursive processing. To do this you have to specify variables with the character **#** after an opening brace: **{#MyVariable}**. More details in this unit below.

By default, RoboTask tries to expand all variables in the specified expression. Then it recursively reiterates the attempt to expand variables in resultant expression until all variables

are expanded. However, sometimes it is necessary to protect a text from expanding variables. These can be some technical texts for automated processing. These texts aren't directly related to RoboTask. They can contain inserts coinciding with the variables of RoboTask. The use of braces is quite a widespread method of inserting some macros when texts are processed automatically.

For example, there is such a text file:

```
To automate mailing you can use macros to create a message:
insert of a customer address - {Email}
insert of a customer name - {User}
insert of a sender name - {SenderEmail}
insert of a current date into the message - {Date}
insert of current time into the message - {Time}
insert of a signature - {Signature}
```

You have to process this text in a cycle together with other files by means of RoboTask. For example, add HTML tags and save it as HTML file preserving all the file contents without changing. It is easy to see that if we try to write the file contents into a variable by means of a system variable **{TextFile(file_name)}**, expressions **{Date}** and **{Time}** will be replaced with current meanings of date and time.

To save a text to a variable without changing, you have to use the symbol **#** after the opening brace: **{#TextFile(file_name)}**. In this case RoboTask doesn't try to expand all variables in the text recursively, but only returns the contents of the text file without changing. Naturally, you also have to use the variable containing the text with the symbol **#**, in order to prevent from expanding expressions in text. For example: **{#CurrentText}**.

2.1.9 How to use variables correctly

This chapter is a short resume about variables.

Usage of variables in expressions

As a rule, when any action is configuring, it is possible to use variables. To specify a variable in an expression (in a string) it is enough to put the variable name within braces "{" and "}".

How it works.

When any action works the RoboTask tries to expand insets of variables in the expression. In other words, it replaces the variable name with the variable value in the expression.

The algorithm is easy:

At first, the program scans the source line for expressions which are put in braces;

If such expressions are found, the RoboTask tries to find the variable value using the variable name and parameters (if the parameters are specified);

If the variable exists, the RoboTask replaces the expression in braces with the found value;

If such variable doesn't exist, the RoboTask leaves the source expression without any changes.

Assigning some value to a variable

Overwhelming majority of actions execute certain operations and demand to save some values

to data transfer in other actions of the task. Specifying the variable name to save the value, the variable name has to be specified explicitly. A variable name is just a set of Latin symbols and figures without any blanks. Braces are not to be specified in this case.

But there is an exception to this rule. Beginning from the version 5.3 a variable name is possible to be formed with using of other variables. But you must understand why it is necessary.

What happens if you specify braces in the variable name (that is, do insets of other variables in the expression):

- The RoboTask computes the final expression which is the variable name. In other words, it replaces expressions in braces with variable values.
- After that, it checks if it is permissible to use the got name as a variable name. Otherwise, the RoboTask generates warning and skips the operation of assigning value.
- Only after checking, the RoboTask assigns the specified value to the variable with such name.

Note: *The usage of such compound names allows to get more flexibility when writing a task in some cases. But if this method is hard to understand, it is better to avoid it. It is necessary only to specify the variable name explicitly without any braces.*

2.2 Macro recorder

RoboTask has powerful tools of interactive automation, such as «Send Keystroke» operations and the mouse actions (Move, Move to object, Click). However, it is obviously not convenient to create an incremental task that implies mouse shortcuts. Sometimes several operations need to be performed as a single block.

For example:

- Activate the contextual menu;
- Select the menu item;
- Click on the needed element of the pop-up dialog.

In a step-by-step configuration, it is rather difficult to hit the required menu item.

To simplify the creation of the interactive mouse shortcuts sequence you can use the automatic macro recording feature by clicking on «Record a macro» button in the task editor. Macro recorder allows automatic recording of the sequence of mouse pointer movements: namely, mouse button ups and downs, pauses between the shortcuts. When the recording is over Macro Recorder transforms the recorded macro into actions and specifies them as the task steps.

To record the mouse shortcuts do the following:

- Open the [task editor](#)^[49]
- Click «Record a macro». At that, all the RoboTask windows will be hidden and the window with start and stop recording buttons will be displayed.

- Click on start recording button  .

- Then make the required mouse shortcuts (mouse pointer movements and pressing the buttons on the required window elements) and click on stop recording button .
- When the recording is over Macro Recorder will recover the task editor window and insert the recorded shortcuts into the editor.

As a rule, the recorded macro is ready to use. However, it is strongly recommended to edit the created steps manually. Macro Recorder records the actions properties exactly as they were made, and that is not always useful for the task creation.

For example, in such action as «[Move to Object](#)^[224]» it is almost always needed to replace the full title bar with the specific title bar fragment. It should be done because the Windows application windows almost always change their title according to the window contents or the context. If the window properties are left unchanged, during the operation flow RoboTask may not find the window according to the properties. In this case, the task will be stopped with an error.

It is also useful to edit the pauses between the operations. As a rule, they can be significantly reduced to speed up the task execution. However, it is not recommended to remove the pauses at all, because you should wait a certain period of time until the application can respond to the mouse shortcut (e. g. load some data or open a new window).

2.2.1 Macro Recorder Settings

You can open the settings dialog of macro recorder by pressing the button 

Record Mouse

If you want to record actions of a mouse, switch on this option.

Mouse record mode

The recording of the mouse actions can be performed in two modes:

- **Smart Mode** – in this mode a macro recorder fixes windows and control elements where mouse clicks take place. Also macro recorder records coordinates concerning the window

and the control element.

- **Use absolute coordinates only** – a simplified mode of recording. In this mode recording only by absolute coordinates of a screen takes place. This mode can be useful in certain cases when elements of a window are absent.

Use Real Pauses Between key presses

If you want to record pressings of keyboard keys, switch on this option.

In certain cases it is important to record pauses between pressings of keys. For example, if you use different combinations of keys to open a dialog window. If the pauses are not important, you can switch off this option. For example, when simply typing a text in entry field. In this case the standard 40 milliseconds pause is used (approx 25 pressings per second).

2.3 Running tasks simultaneously

Each task runs in the background mode independently of other tasks. You can effectively use this feature while scheduling your tasks. Suppose you need to pack several independent folders into different archive files. You can create the following task:

```
Pack "Folder1" into "folder1.zip"  
Pack "Folder2" into "folder2.zip"  
Pack "Folder3" into "folder3.zip"
```

In this case, the task will pack Folder1, Folder2 and Folder3 one by one. That is, each next folder will be processed only after the previous one is packed.

The use of background processes would be more effective. In this case you need to create three different tasks and each of them will pack the corresponding folder. In this case, the main task will look like this:

```
Start task "Pack folder1" without waiting  
Start task "Pack folder2" without waiting  
Start task "Pack folder3" without waiting
```

Running such a task will be the same as running three tasks "Pack folder1", "Pack folder2" and "Pack folder3". Each of these tasks will run independently of the others and the total time of packing all three files will be a bit shorter than in case with successive processing.

2.4 Debugging of the task

In this chapter we will consider some recommendations (guidelines) concerning the debugging of the generated task. If the task consists of 3-5 sequential steps, there is no need for debugging as a rule. But if there are more than 30 steps with loops and branching in the task ([if .. then .. else](#)^[193]), then there are surely hidden mistakes in it, that aren't visible ex facte.

By all means check the generated task by test example.

For lack of experience, it is difficult to reproduce the entire algorithm in the mind, and to write it as a task without any mistakes. To err is human.

Testing is necessary to check workability and correctness of the task. It is possible to check the implementation of the task, for example, by files of the test folder or by files which are easily restored from a backup copy.

The task can be invoked only after checking its correct working. Otherwise you may break working files. Or the task will not work in time, and you will not get a necessary result.

Output of values of variables into the log file or into the screen.

The task often works incorrectly because there is the wrong value in the variable: the empty value or the incorrect one.

In order to make sure the variables are filled in correctly it is possible to verify the values of variables before the implementation of the key actions. It can be done in the process of performing the task by several means:

- Output of values of required variables into the screen before the implementation of the necessary action. You can use the action "Show message" for it.
- Output of variable values or expressions into log of the task. Use the action "Log message".

As a text you can output one or several variables. For example:

```
{MyVar1}  
{MyVar2}
```

Also you can output the whole expression if you use the composite value consisting of some variables. For example:

```
"{CurrentUser}" <{CurrentEmail}>
```

Using of local variables.

It is strongly recommended to use [local variables](#)^[11] in the task. Their advantage is that they "live" only while the task is being implemented, and they are visible only in the context of the implemented task.

Imagine the situation:

You have created a task by copying an existing task. After copying you change the task a bit. All variables in it are global by default. By some reason you have forgotten to change the names of variables. What will happen if both these tasks are implementing at a time? The result must be unpredictable. Both tasks can change the same variables. The algorithm of every single task will be broken.

We can avoid it easily if we use local variables. Choose the tab "Local variables" in the editor of the task and enumerate the variables used in the task, one by one into a line (see the chapter "[Local variables](#)"^[11]).

The global variables are necessary only in two cases:

- To transfer some data into another task.
- To save a variable value between sessions of RoboTask.

In other cases you'd better use local variables.

2.5 Task synchronization

Let us try to make the task described in the previous section a bit more complicated. Suppose you need to pack three folders in three different files and then write them to a CD. As you remember, we have started three different tasks to pack the folders. It means that we must wait until all three tasks are finished before we can write the archives to a CD.

The "Wait for Task" action is used for that. Let us modify our task in the following way:

```
Start task "Pack folder1" without waiting
Start task "Pack folder2" without waiting
Start task "Pack folder3" without waiting
Wait for Task "Pack folder1" for 10 min.
Wait for Task "Pack folder2" for 10 min.
Wait for Task "Pack folder3" for 10 min.
Write files folder1.zip, folder2.zip, folder3.zip to CD
```

Thus, we start three simultaneous processes in order to pack the necessary data and after all three processes are sure to be finished, we write the archive files to a CD.

2.6 Using built-in Basic

Sometimes we need to make some nonstandard calculation, analyze a string or modify it according to a certain algorithm. The Basic programming language will help you in that. The Basic plugin for RoboTask is not included in the main distribution package. You can download it from the [RoboTask site](#) and install additionally.

Basic is a simple and at the same time quite powerful programming tool oriented towards both beginners and professionals. You can use a BASIC script to access user and system variables in RoboTask, as well as other tasks. The BASIC plugin comes together with the full help on the BASIC language. The installation file also includes some sample uses. The description of the [Evaluate](#)^[266] and [Basic script](#)^[267] actions, as well as the mechanism of interaction with RoboTask is described below.

Almost anyone can learn how to write small procedures in the BASIC language. The use of BASIC in tasks extends available actions beyond the set of RoboTask actions. Experienced users can use Windows APIs and third-party COM objects in their procedures written in BASIC without any limitations.

2.7 Running RoboTask as an NT service

2.7.1 Service vs Application

RoboTask can work in two modes:

- As a common application
- As a system service.

Almost everybody knows what a common application is. Many people have an idea about what a system service is. But very often they know only that the service works even if a user has not logged in.

— Yes, it is right. A user session is not necessary for a service. It is, undoubtedly, convenient. But it also puts a number of limitations. And it is necessary to remember about this. Let us consider all the pros and cons.

Fundamental differences between modes of the service and application for RoboTask.

Service and application have different sets of tasks.

RoboTask application keeps its tasks in a user profile. Thereby, every user will have their own set of tasks by default. It is convenient, for example, in the mode of a terminal-server, when several users work on one server in the mode RDC (Remote Desktop Connection). Every instance of RoboTask will work independently from others and not interfering with others.

RoboTask service keeps tasks in its folder in Program Files. To make RoboTask perform necessary actions in the service mode, it is not enough to simply install the service. It is necessary to import or create required tasks for the service as well.

Different sets of tasks allow the application and the service to work simultaneously and independently.

Service and application have different environment.

The application inherits the environment of a user session as any other application which the user has run in their session.

The service uses the environment *LocalSystem*. Despite the fact that you can see both windows application and service on the screen (for example, in Windows 2000 and Windows XP), RoboTask will use different environments in these modes. More details below.

Application mode

After the installing, RoboTask is ready to work in the application mode. By default, RoboTask runs automatically every time when a user opens a user session (log on to Windows).

Advantages

- Additional settings are not necessary; RoboTask is ready to work immediately after installing.
- Easy access to the main window and to the settings of RoboTask.
- The work of RoboTask in the user session allows to get access to the same resources which are available to the user (for example, network folders and disks, windows of other applications, etc.). This is inheritance of a user session environment.

Disadvantages

- In order that RoboTask may begin to work, it is necessary to log on.
- Logging off the session RoboTask also turns off as all other user applications. No tasks are performed after that.
- In operation system Vista and further ones, the system UAC (User Access Control) demotes the privileges of the started applications. It is done to increase security against malware and viruses.

Problems connected with the UAC manifest themselves in a possible error "Access Denied" during some operations. In case of starting certain applications with elevating of privileges (for example, by means of the utility RG.EXE from the package RoboTask) you have to confirm running of programs manually.

The problems of the UAC can be solved in two ways:

- Turning off the UAC. In this case all the applications in the session will work with user privileges. This mode is possible but not recommended because the security of the system against malware decreases
- Running of RoboTask in the mode "As Administrator". It is enough to turn on the checkbox "Run as Administrator" in the dialog Settings (menu Options -> Settings). But in this case you will have to confirm running of RoboTask manually when the UAC requests.

System service mode

To install RoboTask service you can use the utility "[RoboTask Service Manager](#)"^[25] from the package RoboTask. The utility allows to install, delete, start or stop the service. Also the utility allows to specify initial common settings of RoboTask for working in the service mode.

The usage of RoboTask as a system service has unquestionable advantages, but it causes some inconveniences as well.

Advantages

- RoboTask service begins the work when the system starts. There is no need to log on. It is enough just to turn on the computer.
- By default, all the tasks of RoboTask work with system privileges.

Disadvantages

- As a rule, the system service works in a hidden mode. In the system Windows Vista and further systems all interactive services work in a separate system session. A user cannot see the main window of RoboTask without additional manipulations. That complicates manual control of RoboTask.
- By default, services working with the privileges LocalSystem do not have access to network resources (i.e. the network folders on remote computers)
- It is necessary to avoid any interactive actions in service tasks: moving a mouse, pressing mouse keys, sending keystrokes or calling any dialogs.

The first two items cause some inconvenience, but these problems can be solved. See below how to do it.

The last rule is to be fulfilled for the following reasons:

- The system ignores moving the mouse and pressings the keys inside of a locked session. This is done for security of the system. For this reason, the simulation of mouse and keyboard actions will not work if the user session is locked. The user session is locked by default, when screensaver is activated .
- As a rule, a user does not have a direct access to windows of RoboTask in the system service mode. All the dialog windows require to press OK or Cancel. If the user does not do

it, the task comes to a stop and waits for a user action endlessly.

How to get an access to the service in the OS Windows Vista/7/2008/8/2012

Access to the main window of service can be got by means of the system service "Interactive Service Detection". That is described in the chapter "[How to get an access RoboTask Service](#) [32]". Then it is possible to change settings of RoboTask and service tasks.

The owners of Business License can get the access to the service through a local network. That is described in the chapter "[Control of RoboTask through network](#) [38]" and related chapters. The work of a network client of RoboTask is integrated into the main window of RoboTask and must not cause any difficulty.

Initial settings of the service (a number of a port, privileges of access, parameters of authentication, etc.) can be set with the utility "[RoboTask Service Manager](#) [25]".

How to get an access to the network resources in the service mode

By default, the RoboTask service works with privileges LocalSystem and does not have any access to network folders. This problem can be solved in two ways:

1. Start a service with privileges of any user. It can be done in system settings of the service. In this case the service inherits privileges of the stated user (including the privileges within the local network). But then interactivity of the service will be disabled.
2. Take notice that the user is to have the permission "Log on as a service". Input correct parameters of the user on the tab Logon Parameters in RoboTask Service Manager. In this case all started tasks by default inherit privileges of the user. The inheritance can be turned off in Task Editor if necessary. See the parameter "Log on Task as User" on the tab "Advanced".

Summary

Both modes have their own advantages and disadvantages. You can use RoboTask as an application and as a service simultaneously. Thereby, you can fulfill the whole circle of tasks that can be solved by means of RoboTask.

How you will manage the process of automation on your computer or in a local network depends only on your needs.

2.7.2 Installing and running

RoboTask can run in two modes:

- As a regular application
- As an NT service

An NT service is started together with the operating system and runs even if you are not logged on. If you correctly create your tasks and configure triggering events, it will be enough just to switch on the computer for RoboTask to start doing what it is supposed to do. This

mode is important for those computers that are used as servers in your office.

The NT service mode is not available on the Windows 9x/Me platform. The NT service mode is not installed by default. In order to install the RoboTask service, you should use [RoboTask Service Manager](#)^[25] utility.

RoboTask Service Manager allows to start, stop RoboTask service, and make the initial adjustment of the service.

2.7.3 Using UNC names

If you access various network resources in your tasks, we recommend that you use UNC (UNC - Universal Naming Convention) names.

For example, instead of the path

```
z:\documents\report.doc
```

you can use

```
\\server1\incoming\documents\report.doc
```

A UNC name is formed in the following way:

```
\\<Server_Name>\<Resource>\<subfolders>\<file_name>
```

I.e. you should use the name of the server and the name of the resource instead of the disk name ("z:").

What benefits you get:

- A UNC name is always valid within your local area network and does not depend on how network drives are mapped on a particular computer.
- You can use UNC names to access network resources even if you have no connected (mapped) network devices. It is simply necessary in the NT service mode when there are no mapped drives for RoboTask in principle.

2.7.4 Authentication parameters

When RoboTask is running in the NT service mode, it does not see network resources by default. It happens because in this case RoboTask has not the rights of your session account, but the rights of the virtual "SYSTEM" account despite the fact that you can see the green icon in the tray and can manually control the program. To allow the program to log on to the network, you should specify authentication parameters. These settings make sense and are available only in the NT service mode. Open the Settings dialog box (Options | Settings) and switch to the "NT Service" tab.

Also [RoboTask Service Manager](#)^[28] allows you to make this adjustment too.

Log on Process as specified user.

Select this checkbox if you want to allow RoboTask to log on to the local area network automatically when the RoboTask service is started. After that you should specify the authentication parameters.

Domain Name.

Specify the domain name where the user is registered. If the user is registered on the local computer, enter a dot (.) instead of the domain name.

User Name.

Specify the username.

Password.

Specify the password for the specified user.

Try to Logon

To test the authentication parameters and log RoboTask manually, click this button. RoboTask will try to log on using the specified parameters and you will see either "Log on successful" or "Log on failed".

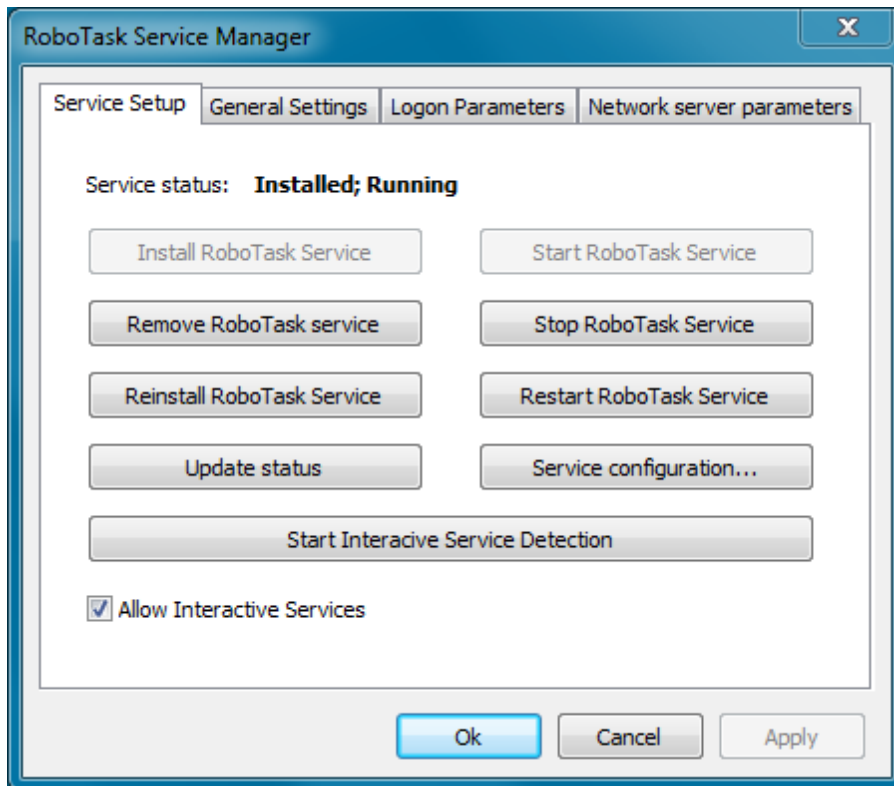

2.7.5 RoboTask Service manager

The RoboTask Service Manager is a separate utility within the installation package of RoboTask. The RoboTask Service Manager allows to install the RoboTask Service and perform the necessary initial settings of the service.

The functions of the service setting are separated according to their subjects onto different tabs.

Service Setup

The functions of installing, starting and stopping of a service are located on this tab. It is also possible to change system settings of the service and to get access to the main window of the service here.

**Install RoboTask Service.**

Installs the RoboTask Service in your system if the service has not installed yet.

Remove RoboTask Service.

Removes the RoboTask Service from a local system.

Reinstall RoboTask Service.

Reinstalls the service with default system settings.

Update Status.

Updates displaying of service status in the window.

Start RoboTask Service.

Starts the RoboTask Service on a local computer.

Stop RoboTask Service.

Stops the RoboTask Service on a local computer.

Restart RoboTask Service.

This operation stops the RoboTask Service, pauses for a few seconds and then starts the

service again.

Service configuration

You can perform system settings of the service here as well as in the system Service Manager (Control Panel => Administrative tools => Services). For ease of operation, the settings of the RoboTask Service are included into this utility.

Start Interactive Service Detection

This function is destined specially for operation systems Windows Vista and the later ones (Windows 7, Windows Server 2008, Windows 8). The function allows to start and stop Interactive Service Detection

The RoboTask service is an interactive service. This means that a user can get an access to the service window and do settings interactively. In the OS Vista (and in later OSs) the system hides interactive services by default. To get the access to the system window it is necessary to start the system service Interactive Service Detection. After that you can get an access to the session SYSTEM and then work with the window RoboTask Service interactively.

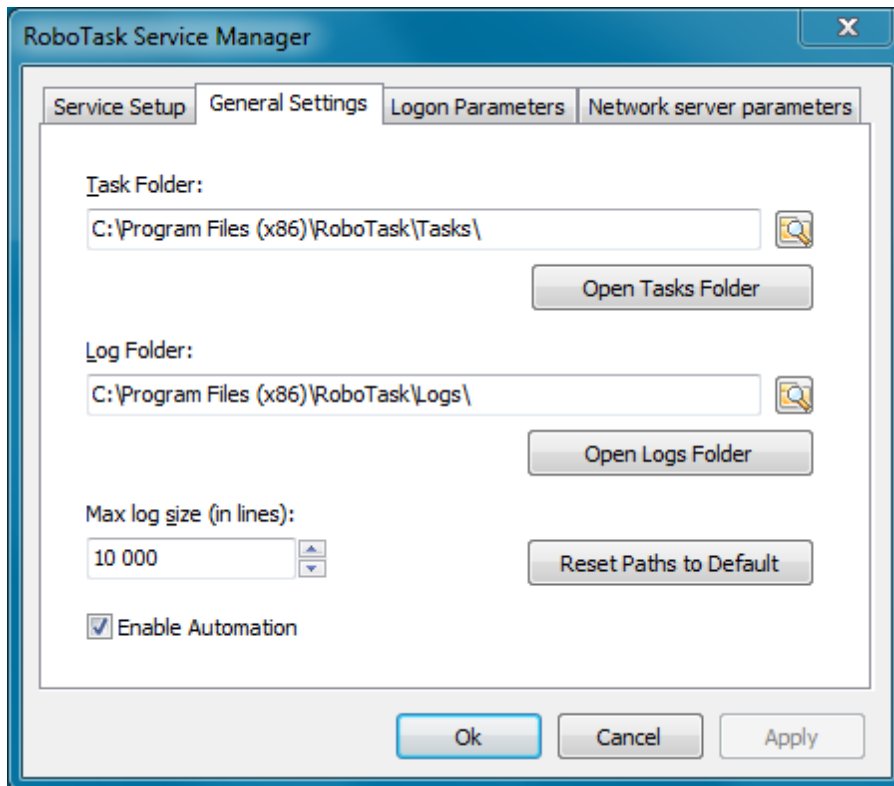

Allow Interactive Services.

To get an access to the service window, interactive services must be allowed in the system. In the OS Windows 7/ Server 2008 R2 (and previous OS) interactive services are allowed by default. In systems beginning from Windows 8 interactive services are *forbidden* by default.

This option does not prevent RoboTask service from working. The service starts and works normally in any case. But if the option is off, you cannot get any access to the main window of the RoboTask service. If interactive services are not allowed, you will get an error when starting Interactive Service Detection.

To allow interactive services in the system it is enough just to switch on this checkbox.

General Settings

You can find general settings for the service on this tab:

- Location of tasks and logs.
- The maximum length of log-files (in lines).
- Switching on and off the automatic work of tasks.

You can also find these settings in the dialog [Settings on the General tab](#)⁵⁶.

Logon Parameters

Logon Process as Specified User

Select this option if you want the RoboTask log on as Specified User and get its privileges.

Domain Name

Enter the name of the domain or server whose account database contains the specified UserName account.

User Name

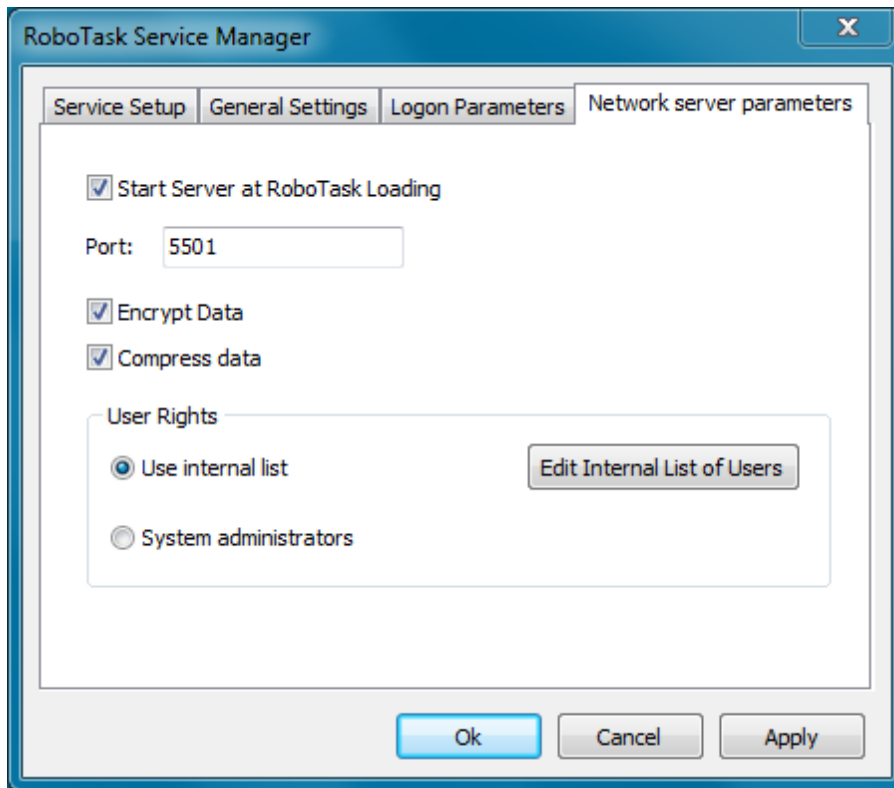

Enter the name of the user account to log on to.

Password

Enter the password of the user account.

Network Server Parameters.

On this tab you can set up server parameters of RoboTask. Read more about client-server mode [here](#)^[38].

Start Server at RoboTask loading

It is on by default. Switch off this checkbox if you want to refuse from remote administration.

Port

This is the number of a port, on which the server accepts connections. By default, it is 5500. If you use more than one instance of RoboTask at your computer, apply different ports to avoid conflicts.

For example: 5500 is for an application, 5501 is for a Service.

Encrypt data

This is the mode of traffic encryption. By default, it is on. The mode of ciphering is specified by server. A client is tuned on the mode of encryption automatically. RoboTask provides the traffic encryption with dynamic keys using CryptoAPI system functions.

Compress data

This is the mode of traffic compression. By default, it is on. The mode of traffic compression can be useful when connection is slow (for example, DialUp or GPRS). The mode of traffic compression (packing) is specified by server. A client is tuned on the mode of compression automatically.

User Rights

This is the check mode of user's rights at connection. It is possible to choose between two modes of user checking:

- Use Internal list. When you press the button "Edit Internal List of Users" in this mode, you can define users, who have the right of connect to the server. This is just text in the form USERNAME=PASSWORD on every line.
For example:
`admin=1234567890`
At the checking of a user, the server inspects presence of the user in a list and correctness of a password.
- System Administrators. In this mode the server checks presence of administrator's rights on a local computer when a client connects.

If the user isn't checked, the server returns an error and closes the connection.

By default, the System Administrators mode is on.

2.7.6 Peculiarities of working in the system service mode

In this chapter we will consider the base differences between the two modes of RoboTask:

- The general application
- System Service

RoboTask is designed so that the application and the service could work at the same time, not preventing each other. When installing RoboTask Service interaction with the desktop is allowed by default. Sometimes this mode of the service tangles understanding.

[Peculiarities of RoboTask Service working under OC Vista/ Windows 7/ Windows 2008 Server](#)^[32]

2.7.6.1 The visual differences between the work in ordinary application mode and in the system service mode

- The RoboTask Service has a green icon in the system tray. The ordinary application has a blue one.
- The main window title of RoboTask terminates in the line "(NT Service)". For example: *RoboTask 3.5 (NT Service)*. The tool tip of the green icon also contains the substring "(NT Service)".
- RoboTask in application mode has another set of tasks than RoboTask Service. The tasks for the application mode are in the local folder of the user's profile (by default). The concrete name of the folder depends on the operating system and on the user name. The tasks for the service mode are in the subfolder <RoboTask_Folder>\Tasks (by default "C:\Program Files\RoboTask\Tasks").

You can see and change the path to the task folder in the settings of RoboTask (the menu Options | Settings)

2.7.6.2 Peculiarities of RoboTask Service working in RDC mode

In RDC (Remote Desktop Connection) mode you can't see the green icon. The system prohibits the interaction of service with desktop in RDC regardless of the settings of service. You can see the green icon and the main window of RoboTask only in the local session (i. e. from the local terminal).

But Windows 2003 Server gives an opportunity to intercept the local session for RDC. It is necessary for it to start up the client RDC with the parameter `/admin`.

The command line is:

```
%SystemRoot%\system32\mstsc.exe /admin
```

To know about the possible parameters you should implement the command:

```
%SystemRoot%\system32\mstsc.exe /?
```

2.7.6.3 Peculiarities of RoboTask Service working under OC Vista/ Windows 7/ Windows 2008 Server

Operation systems Vista/ Windows 7/8/Windows 2008/2012 Server prohibit interaction of services with the desktop within the user's session. After launching of RoboTask you can see the dialog box from system service "Interactive Service Detection" on the screen that the program can't display a message on your desktop. If you click the button "Show me the message", Windows opens the system session where you can see the main window of RoboTask service. Then, as usual, you can tune the work of RoboTask, edit the task list, etc.

You should run service "Interactive Service Detection" manually under the operation system Windows 2008. In addition the manual rerun of the service "Interactive Service Detection" activates the display of the service message on the screen immediately, or in a few minutes. In RDC mode under the OC Window 2008 you can get the access to the RoboTask the same way as from the local terminal. You should run service "Interactive Service Detection". But only users with administrative rights can get the access to the service.

If you don't want to get messages from service "Interactive Service Detection" any more, you can just stop this service.

You can also prohibit RoboTask service to interact with the desktop. Do the following:

- Open the properties of service "RoboTask service"
- Open the tab "Log on"
- Turn off the property "Allow service to interact with desktop"
- Rerun the service.

If you need to change something in the tuning of RoboTask, allow the interaction with the desktop for the RoboTask service.

2.7.6.4 How to get an access RoboTask Service

As we know Windows Vista/7/2008/8/2012 prohibits the interaction with service applications by default.

How to access RoboTask service in this case?

There are two ways to solve the problem

1-st way. By using "interactive service detection" service

- start [RoboTask Service Manager](#)^[25] and start "Interactive service detection". Pay attention that parameter "Allow Interactive Services" must be turned on. Otherwise turn it on and restart RoboTask service.

- You will see this message. Press "View the message"

- You can see RoboTask window in the system session. Configure tasks interactively (or import prepared tasks) and press Return Now button on system dialog.

2-nd way. By using network client.

Run RoboTask Service manager, and setup network server for RoboTask Service. Pay attention that port **MUST be different** from network server settings of application

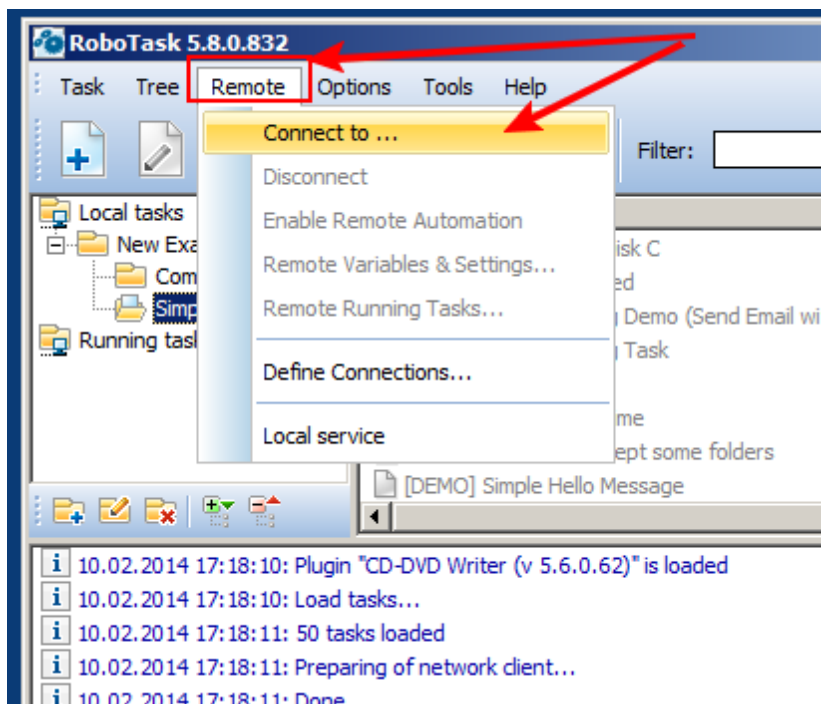

I recommend you to use the next number - 5501

press "Apply" button to save settings and restart RoboTask service.

You can close RoboTask service manager and open main window of RoboTask application.

Choose menu Remote->Connect to...

Input necessary parameters and press "Connect"

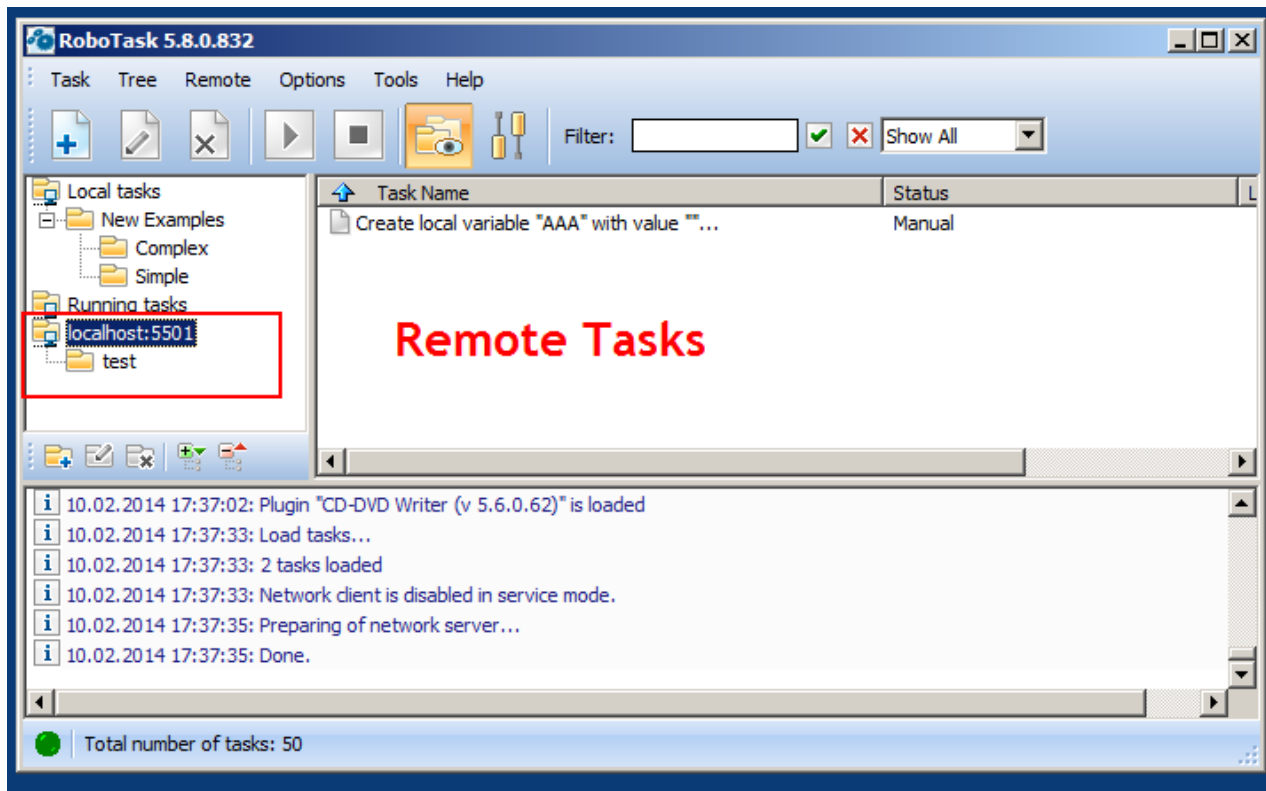

The image shows a dialog box titled "Connect to Remote RoboTask". It contains the following fields and values:

- Computer Name or IP Address: localhost
- Port: 5501
- Domain (for NT authorization only): .
- User Name: admin
- Password: ****

At the bottom of the dialog, there are two buttons: "Connect" (with a green checkmark icon) and "Cancel" (with a red X icon).

You can see new Root folder in the task tree: localhost:5501

You can select it and edit remote tasks (also you can import, run interactively and remove tasks)

2.8 Errors handling

If there is an error occurs in any step during a task, RoboTask records an error message to the task log and stops the task by default. You can change this behavior. To do it, you should select the "Advanced" tab in the task editor and set the "If Error Occurred" parameter to "Continue Execution". In this case, the task will not be stopped in case of an error. The system variable `{IsError}` is used to analyze if there was an error in the previous step. This variable contains "True" if there was an error in the previous step and "False" if there was no error in the previous step.

Another method of the error handling is the starting up of another task when an error is raised. For this purpose you need to tune the task like this:

- Open task editor and go to the tab "[Advanced](#)"
- Choose the point "Run the Error Handling Task" of parameter "If Error Occurred"
- Choose the task in a drop-down list "Error Handling Task".

If an error was raised in any step when you perform the task, RoboTask starts up the handler-task and stops the main task. At the start of the error handler RoboTask passes the next parameters:

- **LastErrorTaskID** – the internal ID of the task, in which an error was raised. It is a formal identifier of the task like a number.
- **LastErrorTaskName** – the name of the task, in which an error was raised.
- **LastErrorTaskExternalName** – an External Name of the task, in which an error was raised.
- **LastErrorStep** – the number of the step (starting from 1), in which an error was raised.
- **LastErrorCode** – code of the error. There is the own kit of codes of errors for any type of

actions (see description of actions). By default – 0.

- **LastErrorDescription** – the description of the error. It depends on a type of action. By default, it is the line "General error".

This set of parameters is enough to definitely identify the error and to undertake any actions. For example:

- Send an email message with the notice and description of error;
 - Make an record into text log file;
- and etc.

The variables *LastErrorCode* and *LastErrorDescription* can be used in the task in which the error occurred.

The conditions of the using are similar to the variable *IsError*: it is necessary to set the parameter *If Error Occurred* into the value *Continue Execution*, to not interrupt the performing of the task when an error appears.

2.9 Control of RoboTask through network

RoboTask has the feature of the controlling over tasks through network. This opportunity is available to owners of the **Business License**. The operation of major components of Client-Server is also available in trial mode for a testing.

The control of remote RoboTask is necessary in the next cases:

- The control of a local RoboTask service. Beginning with Windows Vista, the system forbids interaction between a service and a desktop within a user session. Therefore the control of tasks is related with certain inconveniences (see the chapter Peculiarities of work RoboTask Service under OS Vista/ Windows 7/ Windows 2008 Server). The mode Client-Server permits to edit on-the-fly, to add, to delete, and to start service tasks, and also to view the tasks logs without calling at a system console.
- The control of RoboTask installed at the other network computers. RoboTask in client mode can connect to several instances of RoboTask simultaneously. It allows to view and to edit tasks at the other computers in the main window of RoboTask without using RDC (Remote Desktop Connection) or similar tools.

Notice: At startup of a task at a remote RoboTask the task is performed in the session in which the RoboTask server is working. It can be tracked only on a client the course of performing by the task log. If the task demands some interaction with the program (for example, dialog windows) it can't be done from a client.

2.9.1 Network Server

The server doesn't contain any visual interactive elements and serves only for authorization and handling of client requests. The server must be active if you want to control this copy of RoboTask remotely

All tunings of the server are in the dialog window of [RoboTask Settings](#)^[55] (menu Options | Settings) on the tab "[Network Server](#)^[60]".

Start Server at RoboTask loading

It is on by default. Switch off this checkbox if you want to refuse from remote administration.

Port

This is the number of a port, on which the server accepts connections. By default, it is 5500. If you use more than one instance of RoboTask at your computer, apply different ports to avoid conflicts.

For example: 5500 is for an application, 5501 is for a Service.

Encrypt data

This is the mode of traffic encryption. By default, it is on. The mode of ciphering is specified by server. A client is tuned on the mode of encryption automatically. RoboTask provides the traffic encryption with dynamic keys using CryptoAPI system functions.

Compress data

This is the mode of traffic compression. By default, it is on. The mode of traffic compression can be useful when connection is slow (for example, DialUp or GPRS). The mode of traffic compression (packing) is specified by server. A client is tuned on the mode of compression automatically.

User Rights

This is the check mode of user's rights at connection. It is possible to choose between two modes of user checking:

- Use Internal list. When you press the button "Edit Internal List of Users" in this mode, you can define users, who have the right of connect to the server. This is just text in the form USERNAME=PASSWORD on every line.

For example:

```
admin=1234567890
```

At the checking of a user, the server inspects presence of the user in a list and correctness of a password.

- System Administrators. In this mode the server checks presence of administrator's rights on a local computer when a client connects.

If the user isn't checked, the server returns an error and closes the connection.

By default, the System Administrators mode is on.

Start Server

It starts the server.

Stop Server

It stops the server. At that rate, all opened connections are closed.

View/Edit connections

Here it is possible to view all opened connections and to close selected connections.

2.9.2 Network Client

Network Client is integrated into the main window of RoboTask. At connection to remote RoboTask, a new branch, fitted to the service tasks, is added on the tree of tasks. Subsequent work with network tasks is completely "transparent". That is, you can trigger, edit, and delete tasks, just as if you would work with local tasks.

RoboTask can open several connections at the same time: one connection on each server. All connections are visible at the tree of tasks.

2.9.2.1 Connect to

Choose the menu item [Remote | Connect to](#)^[51] for fast connecting to a server. For connecting it is necessary to specify following parameters:

- **Computer Name or IP address.** It can be also the global network name (for example: www.mydomain.com), if the server is in a global Internet network. One can use the name localhost or the address 127.0.0.1 for access to a local computer (for example, to connect to a local service).
- **Port.** For example, the port number which is specified on the server. By default, 5500.
- **Domain.** This parameter is necessary if only the mode of authorization System Administrators is specified on the server. Specify a domain name or "." (Point) for a local user on the server.
- **User Name**
- **Password**

2.9.2.2 Define connections

If you need to constantly control the group of servers, you can create predefined connections. At that rate, corresponding items of menu Remote appear and then you can connect to the server "in one click."

Choose the menu item [Remote | Define Connections](#)^[55] for creating/editing of predefined connections.

To create a define connection, you need to specify a name of connection for a menu item and then to specify parameters of connection.

If you not switch on the CheckBox "Save Password", RoboTask doesn't save a password for

the next sessions. In this case, when trying to connect, a network client will request a password.

Part

Menus

3 Menus

3.1 Task

3.1.1 Task - New

Allows you to add a new task. After you select the command, the **Add Task** dialog box displays, allowing you to select the following tabs to create a task:

- [Actions tab](#)^[43]
- [Triggering Events tab](#)^[44]
- [Advanced tab](#)^[45]
- [Local variables tab](#)^[47]

Actions tab

Action List

Displays a list of the actions you have selected for the task you are creating or modifying. Click the **Add** button to add an action. Select an action in the **Action List** and click the **Edit** button to modify the action parameters.

When you start the current task, the actions run in the order in which they appear in this list. Click the  &  buttons to move an action up or down in the order listed.

Record a macro

In order to record mouse actions "as is" click this button. [Macro recorder](#) catches mouse actions and saves them as a sequence of task actions.

Add

Place the cursor in a row of the **Action List** where you want to add an action. You can then click the **Add** button to display a list of actions that you can add to the task.

Edit

Select an action in the **Action List** and click the **Edit** button to modify the parameters, or settings, for the action.

Remove

Select an action and click the **Remove** button to remove the action from the task.

Move Step Up

Select an action in the **Action List** and click  to move the action up in the list. This ensures the action runs earlier in the process when the task runs.

Move Step Down

Select an action in the **Action List** and click  to move the action down in the list. This ensures the action runs later in the process when the task runs.

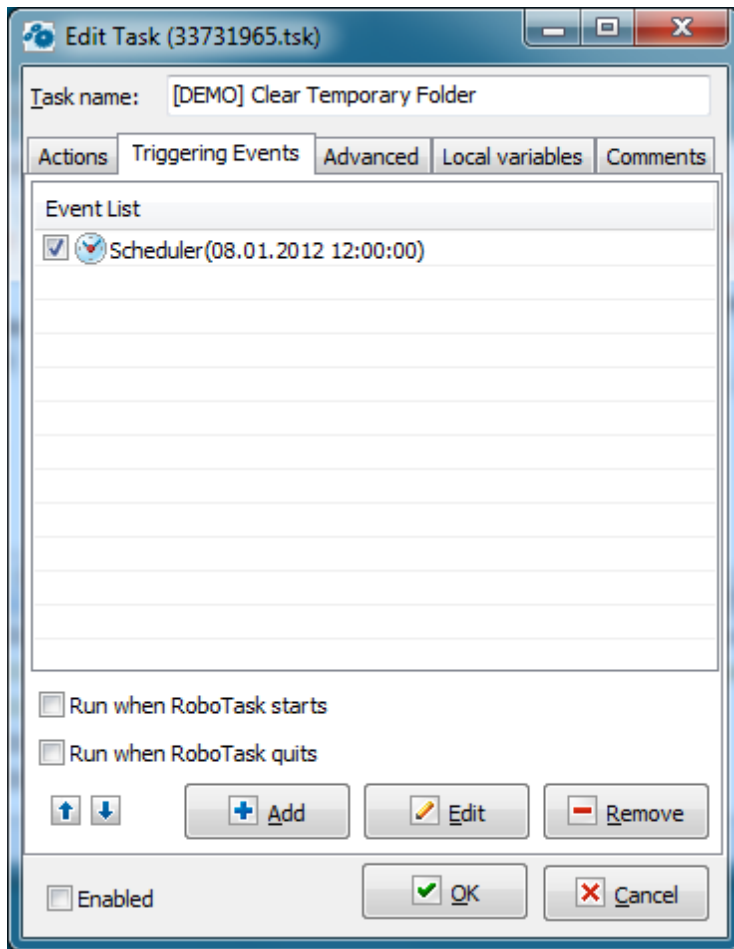

Enabled

If the check box is cleared, the task is disabled and you must run it manually by double-clicking the task in the RoboTask window.

Tip

- To change the **Enabled** setting, select a task in the RoboTask window and right-click.

Triggering Events tab

Event List

Displays a list of the events you have selected for the task you are creating or modifying. The order in which events appear in the list does not matter.

Run When RoboTask Starts

If this check box is selected, the task will run automatically when RoboTask starts.

Run When RoboTask Quits

If this check box is selected, the task will run automatically when RoboTask quits.

Add

Click the **Add** button to display a list of events that you can add to the task.

Edit

Select an event in the **Event List** and click the **Edit** button to modify the parameters, or settings, for the event.

Remove

Select an event and click the **Remove** button to remove the event from the task.

Advanced tab

Log Level

Select the status messages you want to record in the log file:

- **Nothing**
- **Errors Only**
- **Errors and Warnings**
- **All Messages**

Action After Completion

Select an option to run a task:

- **Nothing** - Nothing happens when the task completes all actions.
- **Disable Task** - The task is disabled when the task completes all actions. This is useful if you want to run a task once and save the task to use again later. You can change this later.
- **Delete Task** - The task is removed from the computer permanently when the task completes all actions. This is useful if you want to run a task once and do not need it again. You cannot use the task again when you select this option and run the task.

External Name

You can define an external name by hand. External Name is, per se, an alternative identifier of a task, which can help you to refer to a task ([see object RoboTaskApp₃₆₇₁](#)). RoboTask controls the uniqueness of the External Name and, in case of name clash, resets it to the default value. The default value looks like TaskNNNN, where NNNN – is just an ordinal number.

If Error Occurred

Here you can define the behavior of a task when an error is raised in any step. You can choose from 3 variants:

- **Stop Task** – the default action. When an error is raised, performance of a task is stopping.
- **Continue Execution** – when an error is raised, performance of a task is going on. In other words – it is ignoring of the error. We recommend to use this mode only if it is really necessary.
- **Run the Error Handling Task** – run the other task if an error is raised. The running task, per se, is an error handler. In this case, performance of the main task is stopping. See below the describing of the transferred parameters.

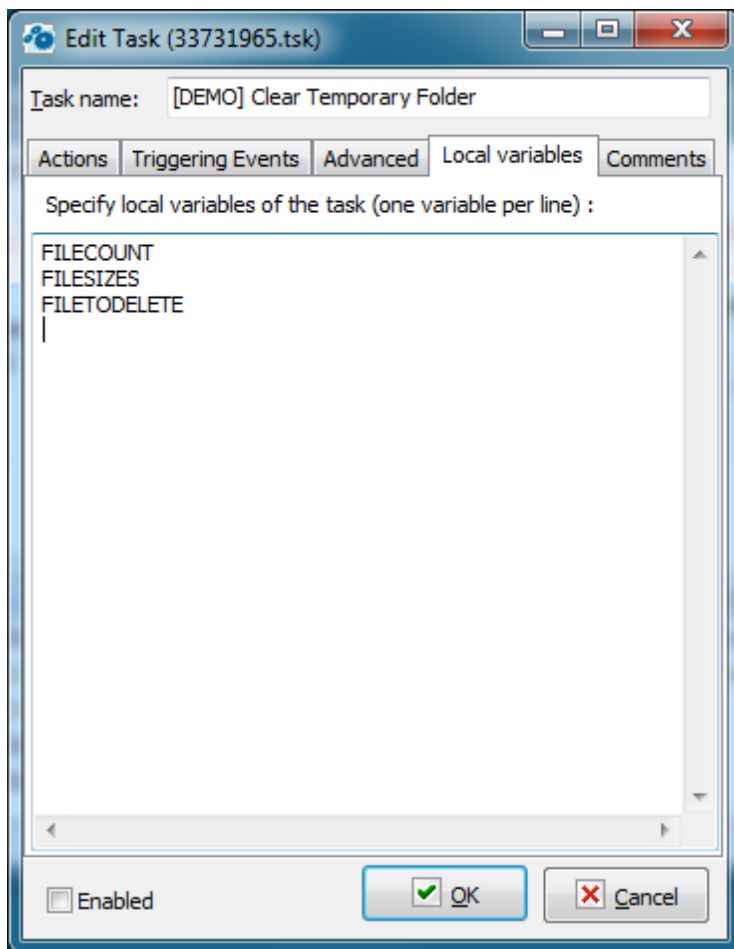

Error Handling Task

Choose the task of error handler in a drop-down list. This task will be started up in case of appearance of error. When the task is being started up, the fixed kit of parameters is transferring to it:

- **LastErrorTaskID** – the internal ID of the task, in which an error was raised. It is a formal identifier of the task like a number.
- **LastErrorTaskName** - the name of the task, in which an error was raised.
- **LastErrorTaskExternalName** – an External Name of the task, in which an error was raised.
- **LastErrorStep** – the number of the step (starting from 1), in which an error was raised.
- **LastErrorCode** – code of the error. There is the own kit of codes of errors for any type of actions (see description of actions). By default – 0.
- **LastErrorDescription** – the description of the error. It depends on a type of action. By default, it is the line "General error".

LastErrorCode and LastErrorDescription depend on a type of action. Descriptions of error codes are put into the help of actions (help file)

Local variables tab

You can declare local variables on the "Local variables" tab of the task editor. There are two ways to declare them:

Enumerate the names of the variables;

Assign initial values to them.

If you enumerate them, just fill the list of names for local variables: one variables per line. For example, like this:

```
LineCount  
FileToUpload  
CurrentFile
```

etc.

To assign an initial value, specify this value after the "=" character. For example, like this

```
LineCount = 0  
FileToUpload = c:\incoming\list.txt  
CurrentFile = note.txt
```

etc.

You can assign initial values not to all variables. By default, local variables contain an empty value (an empty string).

By default, the list of local variables is empty. It means that all variables that are used in a task will be processed as global ones when you run the task. See more information about [local variables](#)^[11].

3.1.2 Task - Edit

Allows you to edit a task. After you select the command, the Edit Task dialog box displays, allowing you to select the following items to edit the task:

- [Actions tab](#)^[43]
- [Triggering Events tab](#)^[44]
- [Advanced tab](#)^[45]
- [Local variables tab](#)^[47]

3.1.3 Task - Delete

Removes a task from the RoboTask and deletes its associated file.

3.1.4 Task - Run

Starts the task that you selected in the RoboTask window. This is useful for testing your task to ensure it runs correctly.

3.1.5 Task - Stop

Allows you to stop the task that you are running in the RoboTask window.

3.1.6 Task - Find the task

This is the service of a quick search of a task by the task name. You can see a dialog with a complete task list. Just begin typing a search string. The dialog will be filtering the task list when typing the string. Only the tasks containing the typed string in their name will be present in the list.

To go to the task, highlight the searched task and press the button OK. You also can jump to the task using the Double-Click on the searched task.

3.1.7 Task - Local running task

This is the service of a search of the task running at the moment. You will see only running at the moment tasks in the list of the dialog window.

To go to the task highlight the searched task and press the button OK or use the Double-Click on the searched task.

3.1.8 Task - Export

Export of a task to an external file. You can also export several tasks. To export tasks highlight the task (or several tasks) in the list and select this menu item. RoboTask will export the tasks into a text file.

3.1.9 Task - Import

Import of a task from a text file to the repository of RoboTask. When you import you will be proposed to select the task file (or several files). The tasks will be imported to the active selected task folder.

Note: Pay attention that the imported tasks are always disabled after importing. You have to enable it manually.

3.1.10 Task - Copy

You can copy a task by means of the method Copy-Paste using the system clipboard. Just highlight one or several tasks in a list and press Ctrl-C (or select this item of the main or context menu).

3.1.11 Task - Paste

If in the system clipboard is the copied task (or several tasks), you can paste them in an active task folder pressing Ctrl-V or selecting this item of the main or context menu.

The method of copying of tasks by means of the clipboard works with remote tasks too if the network connection with remote RoboTask is open. That is you can copy a local task and paste it in a remote session and vice versa.

Note: Pay attention that the pasted tasks are always disabled after the operation. You have to enable it manually.

3.1.12 Task - Duplicate

Copies the task that you have selected in the RoboTask window. This is useful if you want to quickly create several tasks and then edit them.

3.1.13 Task - Create Shortcut on Desktop

Adds a shortcut to the task on your desktop. This is useful if you want to quickly start a task without opening RoboTask window. After you select one or more tasks in the RoboTask window, click **Task > Create Shortcut on Desktop**. The shortcut appears on your desktop with the name of the task.

For example, if you select a task named "Hello, World!" and click this command, a shortcut called "Hello, World!" appears on your desktop.

3.1.14 Task - Create Batch File

Create a batch file to run a separate task from a command line. To create a batch file highlight the task in a list and select this menu item. After that the program will propose to select a folder and a file name.

3.1.15 Task - Exit

Closes the RoboTask window and stops the software.

3.2 Remote

The actions for working with remote RoboTask are collected in this group.

3.2.1 Remote - Connect to

Connecting to remote RoboTask. It is necessary to fill in the fields in the connection parameters window

**Computer Name or IP Address**

The name of a computer in a local network or an IP address explicitly. The IP address should be specified according to the IPv4 standard.

Port

The port for connection. On default, the port of the RoboTask server is 5500 for the RoboTask application and 5501 for the RoboTask system service.

Domain

The name of a user domain for authorization. It is used if the network server of RoboTask uses a system authorization. It is necessary to specify the domain name of the server or a dot (.) if a local user of the server is specified.

User Name**Password**

The parameters of connecting should correspond to the parameters of the RoboTask network server (see the [Server Settings](#)^[60])

3.2.2 Remote - Disconnect

Closes an active connection with the remote RoboTask.

3.2.3 Enable Remote Automation

Switches on or off the automation mode for the remote RoboTask similarly to such function for local tasks ([Tools - Enable Automation](#)^[63]).

3.2.4 Remote Variable & Settings

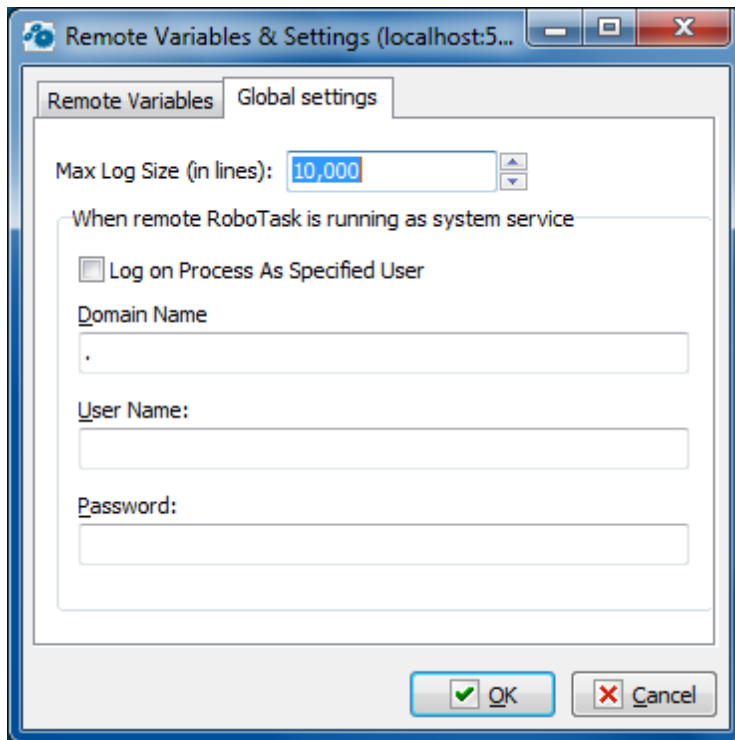

This dialog allows to see and edit the global variables and the global parameters of remote RoboTask.

Remote Variables

You can edit the list of the global variables of the remote RoboTask on the tab of global variables.

Global settings

Max Log Size

The max size of log files in strings. If the size has been exceeded, the older records are deleted.

When RoboTask is running as system service

These parameters are necessary to authorize a process with rights of specified user. These parameters make sense in the system service mode only. If the remote RoboTask is working in the mode of a common application, these parameters are inaccessible.

Log on Process as specified user.

Switch on this checkbox if you want to turn on the authorization mode. Otherwise, RoboTask will work with default rights (SYSTEM). This is quite enough in the most cases.

Domain Name

A domain name or a dot (.) if the local user of the remote computer is specified.

User Name

Password

3.2.5 Remote Running Tasks

Get the list of tasks which are active at the moment in the remote RoboTask. To go to a task, highlight the task in the list and press the button Select. Double-click on the highlighted task performs the jump to the task too.

3.2.6 Define connections

To connect to the necessary server of the RoboTask quickly, you can specify the connect parameters in advance. Predefined connections appear at the end of the menu Remote.

Also see [Network Client](#)^[40] chapter

3.2.7 The list of predefined connections

You can see the list of predefined connections at the end of the menu Remote. Connection occurs in a single click. If you didn't specify any password for the connection, you will be proposed to type the password for the connection.

3.3 Options

3.3.1 Options - View Log

Displays or hides the log window at the bottom of the RoboTask window. The log window shows the results of the task that you run and any errors that occur.

3.3.2 Options - View Toolbar

Displays or hides the buttons at the top of the RoboTask window. These buttons allow you to add, edit, run, and stop tasks.

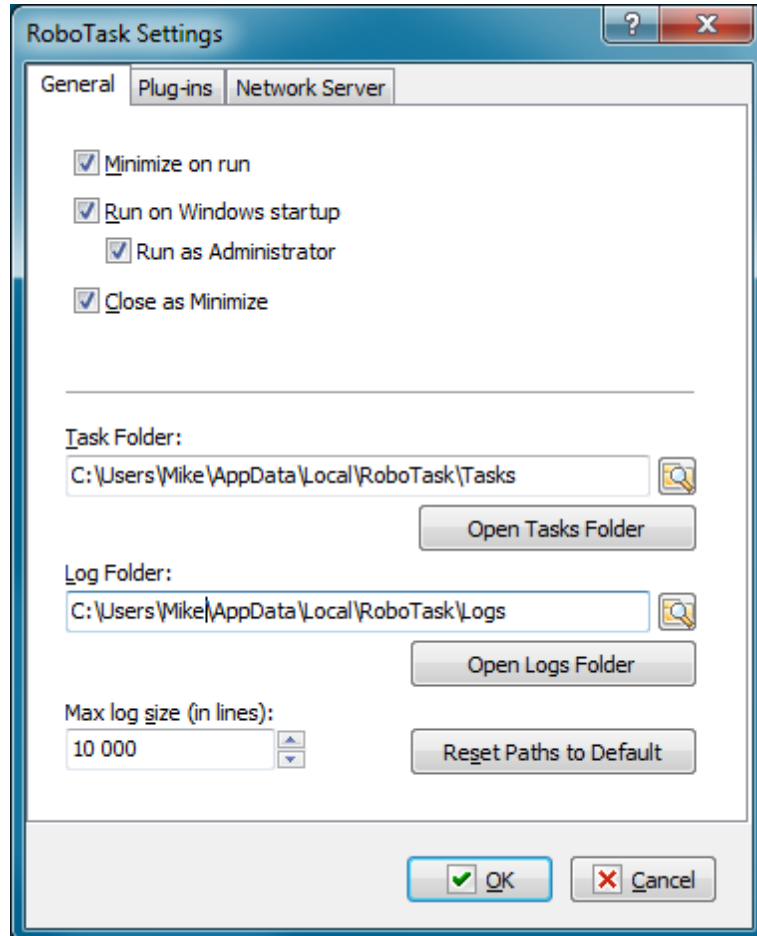

3.3.3 Options - Settings

Allows you to set preferences for RoboTask. You can set preferences for how RoboTask starts, plug-ins, or service mode.

- [General tab](#)^[56]

- [Plug-ins tab](#)^[57]
- [NT Service tab](#)^[58]
- [Network Server Tab](#)^[60]

General tab

Minimize on Run

Click this check box so that RoboTask is minimized when you run the software.

Run on Windows Startup

Runs RoboTask as soon as Windows starts up.

Run As Administrator

This parameter is available only when the RoboTask is used in application mode in the operating systems using the UAC (User Access Control). That is in Windows Vista and the following versions.

If a user has the administrator's rights on the given computer, the UAC, by default, demotes the rights of started applications in the session. Due to this, an error Access Denied is possible during some operations that demand entire rights. For example, when attempting to start or

stop the system services, write down a value in a system register into the branch HKEY_LOCAL_MACHINE\SOFTWARE, etc.

Switch on this flag if you want the RoboTask to run with entire rights. In this case you have to confirm running the RoboTask manually when the UAC requests confirmation.

Close as Minimize

If this option is selected, when you click the X button on the main window caption, RoboTask will minimize. This is useful for preventing of casual closing of RoboTask.

Task Folder

Set the folder where you want to save tasks that you create. You can click the browse button to select a folder.

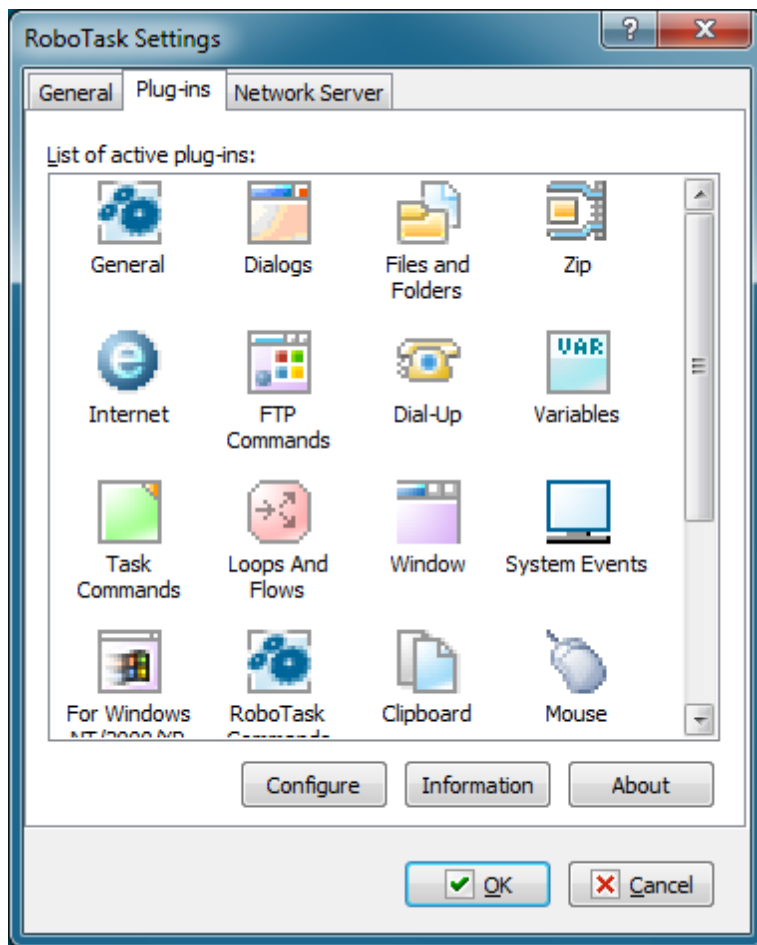

Log Folder

Enter a folder where you want to save log files. You can click the browse button to select a folder.

Max Log Size (in Lines)

Enter how many lines of data to record in a log file. For example, if you enter 300, the log file will contain no more than 300 lines of text.

Plug-ins tab

List of Active Plug-ins

Displays a list of available plug-ins for RoboTask. You can get more information when you click the **Information** or **About** buttons.

Configure

Select a plug-in from the **List of Active Plug-ins** box and click **Configure** to enter settings.

Information

Displays a list of components for the plug-in that you have selected in the **List of Active Plug-ins** box.

About

Displays information about the company or authors of the plug-in that you have selected in the **List of Active Plug-ins** box.

Service tab

On Windows NT, Windows 2000 and Windows XP you can run RoboTask as a Service. An Service is a background process that is loaded by the Service Control Manager of the Windows NT operating system. Services are usually loaded when Windows boots up, before anyone logs on.

Service mode is useful if you want to run a process in the background. However, services are background programs that run all the time and are activated automatically when Windows NT boots up. Services stop when Windows NT shuts down.

You can tune the save setting of RoboTask service by using [RoboTask Service Manager](#)^[28].

The screenshot shows the 'RoboTask Settings' dialog box with the 'NT Service' tab selected. The dialog has a title bar with a question mark and a close button. Below the title bar are four tabs: 'General', 'Plug-ins', 'NT Service', and 'Network Server'. The 'NT Service' tab is active, showing a section titled 'When RoboTask is running as NT Service'. Inside this section, there is a checkbox labeled 'Log on Process As Specified User'. Below the checkbox are three text input fields: 'Domain Name' (containing a single dot), 'User Name:', and 'Password:'. A 'Try to Log on' button is located below these fields. At the bottom of the dialog are 'OK' and 'Cancel' buttons.

When RoboTask is Running as NT Service

Allows you to specify settings when you want to run RoboTask as a Service.

Logon Process as Specified User

Select this option if you want the RoboTask log on as Specified User and get its privileges.

Domain Name

Enter the name of the domain or server whose account database contains the specified UserName account.

User Name

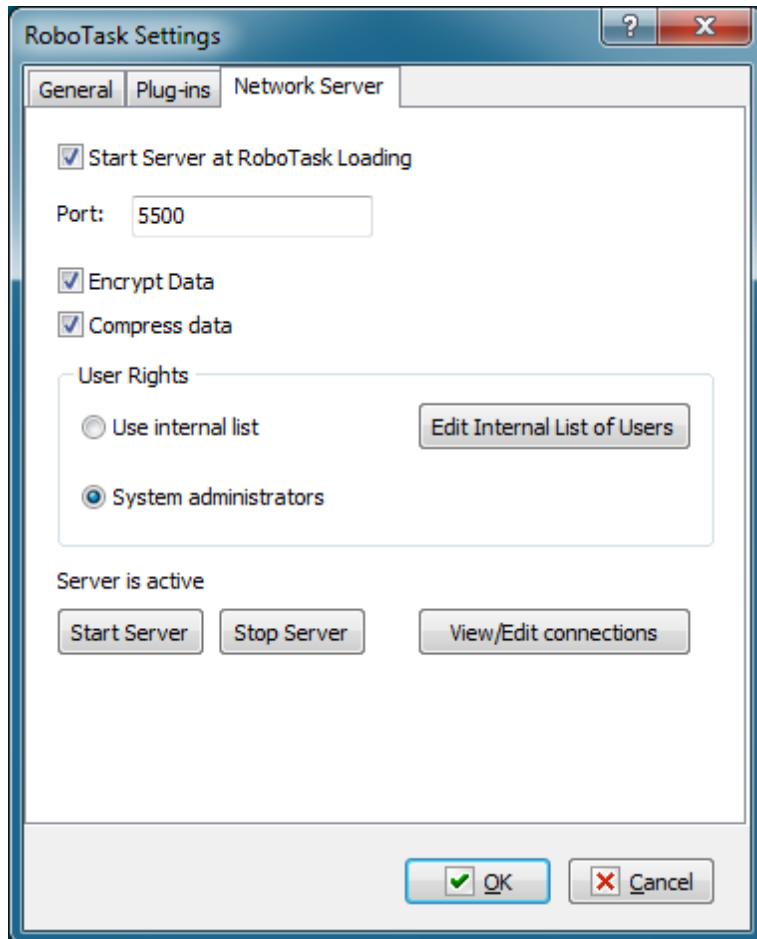

Enter the name of the user account to log on to.

Password

Enter the password of the user account.

Network Server tab

On this tab you can set up server parameters of RoboTask. Read more about client-server mode [here](#)^[38].

Start Server at RoboTask loading

It is on by default. Switch off this checkbox if you want to refuse from remote administration.

Port

This is the number of a port, on which the server accepts connections. By default, it is 5500. If you use more than one instance of RoboTask at your computer, apply different ports to avoid conflicts.

For example: 5500 is for an application, 5501 is for a Service.

Encrypt data

This is the mode of traffic encryption. By default, it is on. The mode of ciphering is specified by server. A client is tuned on the mode of encryption automatically. RoboTask provides the traffic encryption with dynamic keys using CryptoAPI system functions.

Compress data

This is the mode of traffic compression. By default, it is on. The mode of traffic compression can be useful when connection is slow (for example, DialUp or GPRS). The mode of traffic compression (packing) is specified by server. A client is tuned on the mode of compression automatically.

User Rights

This is the check mode of user's rights at connection. It is possible to choose between two modes of user checking:

- Use Internal list. When you press the button "Edit Internal List of Users" in this mode, you can define users, who have the right of connect to the server. This is just text in the form USERNAME=PASSWORD on every line.
For example:
admin=1234567890
At the checking of a user, the server inspects presence of the user in a list and correctness of a password.
- System Administrators. In this mode the server checks presence of administrator's rights on a local computer when a client connects.

If the user isn't checked, the server returns an error and closes the connection.

By default, the System Administrators mode is on.

Start Server

It starts the server.

Stop Server

It stops the server. At that rate, all opened connections are closed.

View/Edit connections

Here it is possible to view all opened connections and to close selected connections.

3.3.4 Options - Variables

Allows you to define variables for RoboTask. This command also displays a list of system variables available in RoboTask.

- [System Variables tab](#)^[62]
- [User's Variables tab](#)^[62]

Variables are strings that contain information such as drive, path, or file name. Variables can control the behavior of various processes. For example, the {TEMPDIR} system variable specifies the location where processes, such as tasks or programs, place temporary files.

You can not modify System variables, but can add, modify, or remove your own variables on the **User Variables** tab.

System Variables tab

The **System Variables** tab displays a list of the system variables.

Categories

Displays a list of all the system variables and their values. You can click **[All]** to see a complete list or click one of the following categories:

- **Date & Time**
- **Files & Folders**
- **System Info**
- **Window**
- **etc...**

Variables

Displays the system variable names and their descriptions.

User's Variables tab

**Name**

Displays the name of the user variables that you create.

Value

Lists the value of the user variables that you set when you create or modify the variable.

Add

Allows you to create a new user variable to use in many tasks.

Edit

Allows you to edit the value of a variable.

Remove

Allows you to remove the selected variable.

3.4 Tools

3.4.1 Tools - Enable Automation

If this option is cleared, the tasks will not run automatically, i.e. all your tasks are disabled. You

may run tasks only manually.

3.4.2 Tools - Lock Task Editor

Locking of functions of task editing. The next functions are blocked in this case:

- Editing of tasks.
- Editing of a tasks tree.
- Editing of a global variables list.
- Import of new tasks.

Thereby, RoboTask goes to the Read-Only mode.

When you switch on the locking, you will be proposed to type the password of unblocking twice. Remember this password without fail.

3.4.3 Tools - Enable All Tasks in List

Enables all tasks that are listed in the current task folder. To enable one task, double-click it and, in the appeared dialog window, select the **Enabled** check box and click OK.

3.4.4 Tools - Disable All Tasks in List

Disables all tasks that are listed in the current task folder. To disable one task, double-click it and, in the appeared dialog window, clear the **Enabled** check box and click OK.

3.4.5 Tools - Start selected tasks sequentially

Starting of highlighted tasks sequentially. The tasks will be started according the list. The next task will be started only after finishing the previous one. This mode is sometimes useful for the manual start of tasks.

3.5 Help

3.5.1 Help - Help Topics

Displays this RoboTask Help.

3.5.2 Help - Send Bug Report

Displays a dialog window which allows to send a report about a bug you found to the developers of RoboTask. Enter information about a problem and then click the **Submit** button.

3.5.3 Help - Technical support

This menu item redirect you to the page of a support site of the product.

There you can get links to additional information about the product, ask a question or go to our forum.

3.5.4 Help - Check for updates

Get the information about updates of RoboTask for your version. On default, checking for updates occurs one time a week. You can specify another periodicity or switch on the manual check mode.

3.5.5 Help - About

Displays information about your version of RoboTask.

Part

IV

Actions

4 Actions

4.1 General

4.1.1 Run Program/Open Document

Use this action to run the application or open a document that you specify. If a document is specified, the application associated with the document opens it.

Run Program/Open Document is one of the most commonly-used actions in RoboTask and one of the most powerful. The most common usage is to start an application or open a document and then send keystrokes or perform other interactive actions. For example, you can use this action to open a log file in Notepad immediately after you back up your files.

Program or Document File Name

Enter the file name of the target application or a document. If a document file is specified, the associated application is used to open it.

Parameters

Enter the parameters, if any. If the **Program or Document File Name** box specifies an executable file, you can specify the parameters to be passed to the application. The format of this parameter is determined by the application. If **Program or Document File Name** box specifies a document file, the information in the **Parameters** box is ignored.

Default Folder

Specifies the default folder to start the task in. If not specified, the folder of the application is used.

Window

Specifies how an application is displayed when it is opened.

Wait Options

There are three choices:

- **Don't wait** - the next action executes immediately after the program starts.
- **Wait until the application is ready for input** - the next action executes only after the program started and is ready for input. This option is useful when you want to perform any interactive actions like [Send Keystrokes](#)^[72].
- **Wait until the application exits** - the next action executes only after the program exits.

Assign Exit Code to Variable

You can assign exit code of running program to variable. This has a sense only if you set "Wait until the application exits" wait option.

If Exit Code <> 0

Usually exit code of command line utility equals to 0. Usually this means that executing of the program is OK. Non zero exit code may indicate that some problem has occurred at runtime.

You can choose one of three options:

- **Nothing**
- **Stop the task** - if exit code is non-zero RoboTask stop the task
- **Raise the Error** - if exit code is non-zero RoboTask raises the error with code 1 and description "Exit code is not equal to 0" (also see [Error Handling](#)^[37])

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.1.2 Run Command-Line Utility

This action is intended for console command utilities. Sometimes it is important not only perform such utility with certain parameters but analyze output data, that is, the text displayed on the screen by the utility.

The action allows to save an output stream of the utility into a variable. Then in the task you can save this information into a file or analyze the output text.

Program Name

Specify the file name of an/the utility. Unlike the action Run Program/Open Document Parameters, it is prohibited specifying of a document file in this field. Only the name of the executed document must be specified here.

You can specify the parameters of a command line here. For convenience, it is possible to type each parameter on a new line. When executing the action, the RoboTask forms the common parameter line from multi-line text.

Default Folder

Specify the folder name, which will be current when the utility starts.

Assign the Output Text into Variable

If you need to save the output text, switch on this checkbox and specify a variable name. Then you can use this variable for the next processing.

Convert to ANSI format

Some utilities output a text with non-latin symbols in OEM format (or in the format DOS). In this case switch on this checkbox for automatically transformation of the string in ANSI coding.

Assign Exit Code into Variable

If you need to save the exit code of the utility into a variable, switch on this checkbox and input the variable name. The exit code is a number. As a rule, it is 0 when it works regularly or an error code when some trouble appears. It depend on the started utility.

If Exit Code <> 0

The action when the exit cod is not 0. Select one of the 3 alternatives:

- Nothing
- Stop the task
- Raise the Error.

On default it is Nothing

4.1.3 Print Document

Use this action to print one or more document files, such as Microsoft Word .Doc files, to the default printer. For example, you can use this action to automatically print daily backup logs.

To print a document, the Print Document action uses a default application for the specified kind of documents. For example, for a Word document (DOC file) it is usually the MS Word from the MS Office package, for a PDF file it is the Acrobat Reader, etc.

The action can direct a document to any printer registered in the system. Of course, the default application is supposed to support printing on the specified printer. As a rule, all the basic applications support this function.

Files to Print

Enter the files that you want to print. This is a required option. Wildcards are allowed. Click the Plus button to add files to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

To printer

- **Default printer** – direct a document to a default printer;
- **This printer** – direct a document to the specified printer. When you select a printer you can pick out the one from a dropdown list or write the name of the printer in the entry field. When writing the name of a printer, variables can be used. For example, {PrinterName}.

Wait options

This parameter defines the timeout in seconds to wait until the document is being printed. You

can also specify an infinite timeout.

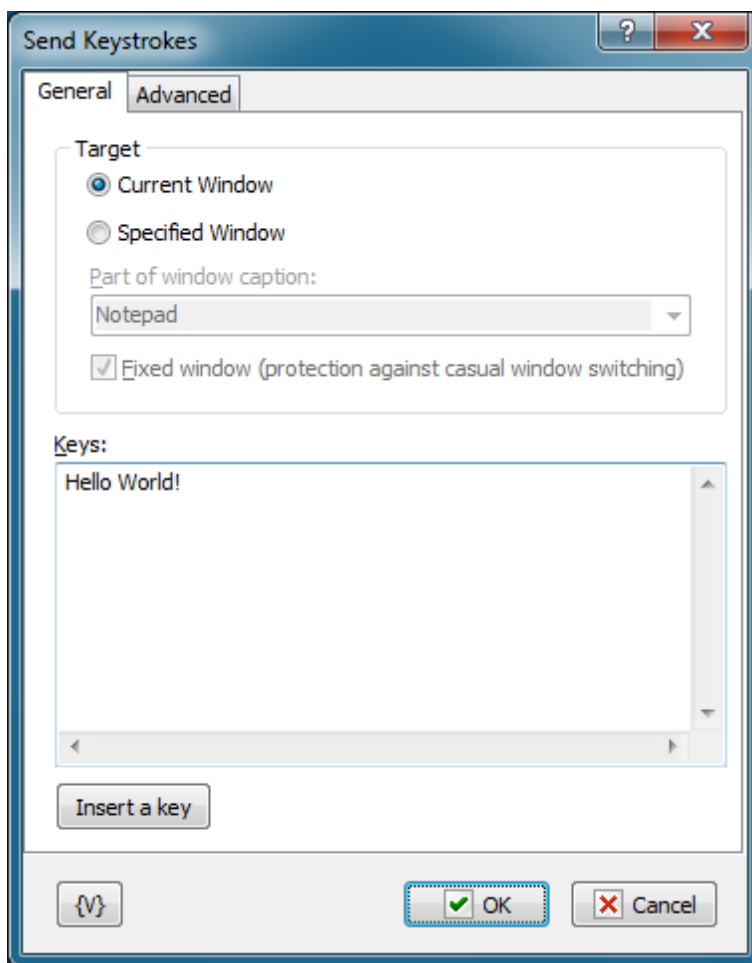

If the timeout is over, the action stops the printing application.

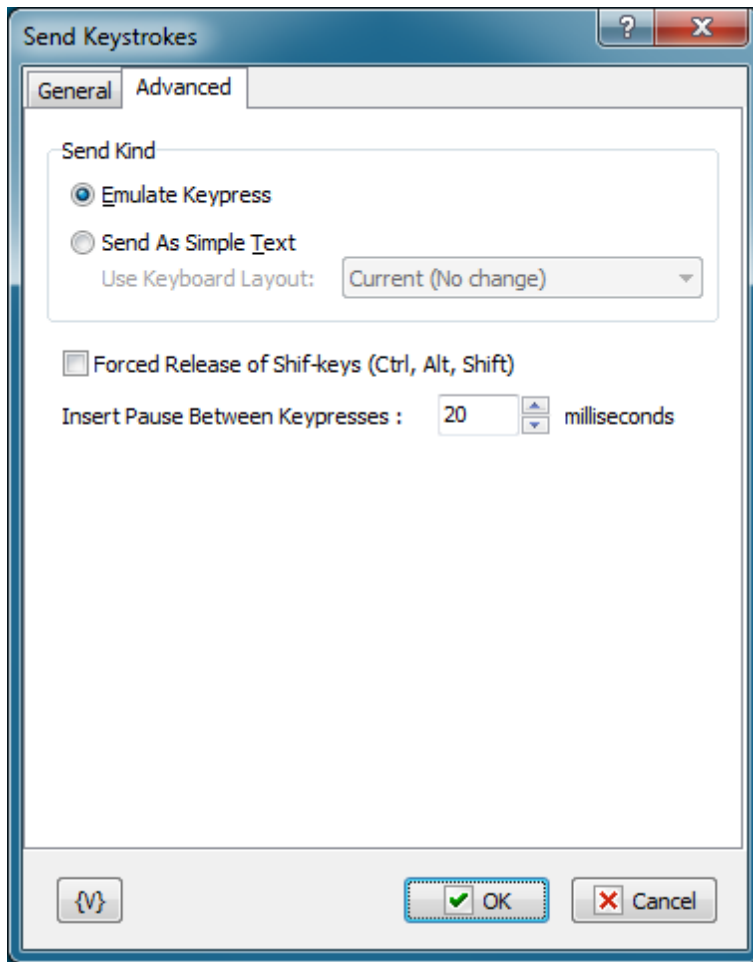

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.1.4 Send Keystrokes

Sends keystrokes to a window that you specify or the window that is currently in focus. After you have opened an application programmatically, you can use this action to access menu commands using shortcut, or hot, keys, such as ALT + F to open the **File** menu. **Send Keystrokes** is one of the most powerful actions for manipulating applications.

Target

Specifies the window to send the keystrokes to. There are two choices:

- **Current Window** - the keystrokes are sent to the currently focused window.
- **Specified Window** - the specified window will be focused and the keystrokes are sent to it.

Part of Window Caption

Enter the caption, or part of the caption, of the window to send keystrokes to. This option is available only when you the Specified Window option is selected.

Fixed Window

Click this check box when you want to prevent a user from switching windows during the time that the action runs.

Keystrokes

Specifies the keystrokes that the action sends to the window. For the alpha-numeric characters, type these keys on the keyboard. For the special keys, such as Esc, F11, Left Arrow Key, and Ctrl+Alt+A, click the **Insert a Key** button.

Insert a Key

Click this button to insert special keys such as Esc, F11, Left Arrow Key, and Ctrl+Alt+A. You can also insert a pause between keystrokes to give time for program operations, such as opening a file.

Send Kind

You can send keystroke in two ways: Emulate Keypresses or As Simple Text. The question is that different programs response on the simulation of keystroke differently.

- **Emulate Keypresses** –RoboTask emulates a hardware keystroke in this mode. It is possible to send keys combinations with Ctrl, Alt, Shift in this mode. Please note, that symbols ^, %, +, #, {, }, (,) are used for recording keys combinations. These symbols are reserved for this mode. How to simulate sending of these keys is shown below.
- **Send As Simple Text** – simulation of a simple typesetting is produced in this mode. The text is sent as is, without using combinations. Pay attention that the sending of key presses is sensitive to the current Keyboard Locale.

Forced Release of Shift-keys

Switch on this parameter, if you want to make forced release of Shift-keys. You can turn off this parameter if you want to send some keystrokes when some of Shift-keys are held down (see [Shift Keys State](#)^[75]).

Insert Pause Between Keypresses

Insert pauses between separate keys presses in milliseconds. This is important particularly for the "Emulate Keypresses" mode. Pauses are necessary to give the application some time for response to the press of keys or keys combinations. By default, 20 milliseconds are preset. As a rule, this is enough for most cases.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Standard keys for GDI windows

When you work with emulated key presses, we recommend that you use standard key combinations for controlling dialog boxes. These combinations work in most dialog boxes in Windows applications and you will not have to use the mouse.

- Tab** – move to the next control element of the dialog box;
- Shift-Tab** – move to the previous control element of the dialog box;
- ESC** – the same as a click on the Cancel button in most cases;
- Enter** – the same as a click on the OK button in most cases;
- Ctrl-Tab** – move to the next tab if the dialog box contains tabs;
- Ctrl-Shift-Tab** - move to the previous tab;

Key combinations

Ctrl	- ^(<Letter>), e.g. Ctrl-S -> ^(S)
Alt	- %(<Letter>), e.g. Alt-W -> %(W)
Shift	- +(<Letter>), e.g. Shift-W -> +(W)
Win	- #(<Letter>), e.g. Win-E -> #(E)

How to simulate reserved symbols: ^ % + # { } ()

You can do this by using *Shift* combinations, like this

^	- Shift-6, i.e. +(6)
%	- Shift-5, i.e. +(5)
+	- Shift=, i.e. +(=)
#	- Shift-3, i.e. +(3)
{	- Shift-[, i.e. +(I)
}	- Shift-], i.e. +(I)
(- Shift-9, i.e. +(9)
)	- Shift-0, i.e. +(0)

Also it's possible to use these symbols within braces

^	{^}
%	{%}
+	{+}
#	{#}
{	{{}
}	{}}
({(}
)	{)}

For example to print the string: ^ % + # { } ()

use the combination: **{^} {%} {+} {#} {{} {}} {({} {})}**

4.1.5 Shift Keys State

This action serves for imitation of retention of Shift-keys in pressed condition or in forced release. Shift-keys are used in various combinations: Shift, Ctrl, Alt, Win-key. Some programs use complex combinations.

For example:

- when Ctrl is pressed, push K and C sequentially
- pressing Left Button of a mouse when Ctrl and Alt are held down

The action "[Send Keystrokes](#)⁷²" can't ensure imitation such combinations.

Action

Select a necessary action:

- **Release selected keys** – forced release of specified keys.
- **Hold down selected keys** – pressing of specified keys and holding them in pressed condition, until you see the action Release of Keys. Please note that all Shift-keys will be released, if you switch on the parameter "[Forced release of Shift-keys](#)^[72]" when Send Keystrokes are in use.

Keys

Mark necessary keys in any combination.

4.1.6 Log Off

Completes one of the following actions:

- Logs off the current user,
- Shuts down the computer,
- Restarts the system.

For example, you can use this action to automatically shut down a computer every night after your defragmenter program finishes cleaning up your hard drive.

**Action**

Select one of the following values:

- **Shut down the computer**
- **Shut down the computer and power off**
- **Restart the computer**
- **Log Off**
- **Suspend** - sleep mode
- **Hibernate** - hibernate computer if it's possible.

4.1.7 Pause

Waits for a specified number of milliseconds and then continues executing tasks. This action is useful when you want to perform extensive operations that require a delay between actions.

For example, you might want to create a pause between printing a document and closing it to prevent a printer error. This pause allows time for the document to pool.

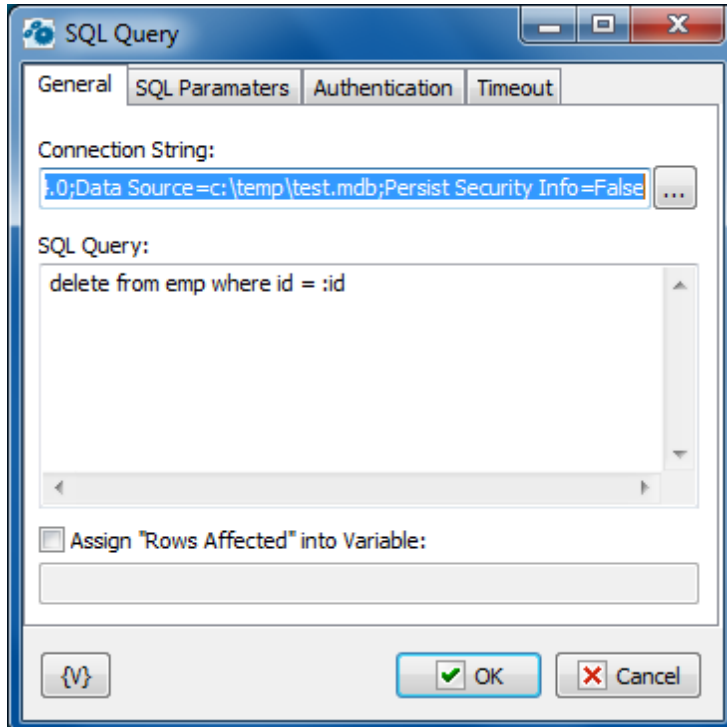

**Pause**

Enter the pause. You can specify the dimension as:

- Milliseconds
- Seconds
- Minutes

4.1.8 SQL Query

Executes an SQL query. This action is useful when you want to update a database. If you want to SELECT from a database, use the [Dataset Loop](#)^[190] action instead.

Connection String

A string with attribute/value pairs for information required to log on to a database and point to a specific database. Click the browse button to open the Microsoft **Data Link Properties** dialog box. You can press F1 to access Help about this dialog box.

SQL Query

Enter the query string in SQL syntax.

SQL parameters

Sometimes using of parameters of a query is more convenient instead of generation of the query by means of variables. For example, when the variable value contains quotes or another special symbols. If you use variables (or macro substitution) when forming SQL inquiry, availability such symbols can "break" the syntax of the query and you will get a runtime error.

Parameters SQL are designated in the inquiry by means of colon (:) before the parameter name.

For example:

```
Select * from employee where hiredate > :dt and salary >= :amount
```

:dt and :amount are parameters of the query.

Parameters can be several types:

- **String** – any string
- **Integer** – an integer number
- **Float** – a real number or the number with a floating dot.
- **Boolean** – a logical value True or False.
- **DateTime** – a date and time. The value of such parameter must be defined in current system format of date and time (see the system regional settings). Notice that using of date-time can have its own characteristics for different databases. For example, it is better specify such parameters for the MySQL as a string parameter in the format YYYY-MM-DD or YYYY-MM-DD hh:nn:ss.

Fill from SQL

Fill the list of parameters from the current query. If a parameter is already in the list, this parameter will be without change. The function fills only the missing parameters in the list.

Add

Add a parameter manually. You will be proposed to type or select from the list the parameter name, select the parameter type and input an expression as the parameter value.

Using of variables in a parameter name and in its value is allowed. The RoboTask will substitute variable values instead of variables before performing the SQL.

Edit

Edit the properties of the selected parameter.

Delete

Delete the selected parameter from the list.

If you specify the parameter which is absent in the query, the action ignores this parameter when performing and writes the proper warning in the log of the task.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.1.9 Wait for Process Finish

Pauses the task and waits until the selected process (processes) is finished. After the monitored process is finished, the task is resumed. If the specified process is not in the memory at the moment when the action is due, the task is not paused.

This action is necessary to synchronize your task with an external application. For example, you may need to wait until the packing program finishes its work before you can copy the packed file to the Backup folder.

Process

You can either select the process from the list of processes that are currently running or type its name manually. You do not have to write the full path to the EXE file if it does not matter where this application was launched from.

If more than one matching process

If there are several running processes matching the specified one at the moment when the action is due, you can specify one of three modes

- **Wait for Oldest** - wait until the process launched first from the matching group is finished;
- **Wait for Newest** - wait until the process launched last from the matching group is finished;
- **Wait for All** - wait until all matching processes are finished.

Waiting

This parameter defines the timeout in seconds to wait until the process is finished. You can also specify an infinite timeout.

If the timeout is over, but the process is not finished, the action will generate the following error: Timeout is over.

Assign Exit Code of Process to Variable

If you select waiting for one process (Wait for Oldest or Wait for Newest), you can assign its exit code to a user variable. A lot of console utilities (for example, packing software) can use this code to inform the application that initiated them about errors in their work.

4.1.10 Wait for Process Start

Pauses the task and waits until the selected process is started. Unlike action "[Wait for Process Finish](#)", this one waits for the appearance of the specified process in memory. If that process is there already, there is no waiting, and control is passed to the next step of a task.

Process

Specify or select from the list the name of the process that needs waiting for. You can use variables.

If you specify the name of EXE-file with a full path, RoboTask will look for the process in memory by its full name. If the path is not specified, RoboTask will look for the process only by the name of the EXE-file without a path.

Waiting

Specify the timeout, during which you need to wait for an appearance of the process. You can specify a timeout in seconds or select the value "Infinity". If the process does not appear in memory during specified time, the action generates an error type "Timeout error. Process didn't start"

4.1.11 Terminate Process

Forces the specified process to be terminated. This method is not a normal way to exit Windows applications. To exit some application normally, you will have to close the main window of this application. (see the operation Window command).

Note:

When you force a process to be terminated, you may lose data (for example, a process is terminated when a file is being saved) or system resources occupied by the process may remain occupied. In this case, multiple process termination may result in very unpleasant consequences. Although quite often it is a safe procedure.

Process.

Enter the name of the process that should be terminated. If the process already exists in memory, you can select it from the drop-down list. The name of the process coincides with the name of its EXE file. There is no need to specify the full path in the process name. If you do not specify the full path, RoboTask will search for the specified process without taking into account its path. Also, you can use variables when specifying the name of the process.

If more than one matching process.

Specify what should be done, if there are several matching processes in memory at the moment of the operation. For example, you started several instances of Notepad.exe with different text files.

There are three options to choose from:

Terminate Oldest – terminate the process started first;

Terminate Newest – terminate the process started last;

Terminate All – terminate all matching processes.

4.1.12 Comment

This action does nothing and is used only as a visual comment for the task.

4.2 Dialogs and Notifications

4.2.1 Show Message/Play Sound

Displays a message box that displays custom text or plays a sound file. For example, you can use this action to display a message and play a sound every time your backup finishes archiving the files.

Tip

- The message box displayed by this action has an **OK** button. You can display a message box with a **Yes** and **No** button with the [Question Dialog](#)^[86] action.

Show Message

Click this check box to display the message box.

Message Text

Enter the text for the message box.

Message Icon

Select the style of the icon for the message box:

- **Exclamation**

- **Information**

- **Question**

- **Error**

**Play Sound**

Click this check box to play a sound. When you click the check box, you can click the browse button to select a .wav file on the computer.

Test

Click this button to ensure that the parameters for the current action work.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.2 Question Dialog

Displays a message box with specified text and two buttons: **OK&Cancel** or **Yes&No**. For example, after your system is backed up, you can use this action to display a message asking you if you want to open the log file.

Question Text

Enter the text for the message box.

Buttons

Click to set the style of buttons that appear on the message box.

- **OK & Cancel**
- **Yes & No**

Action

Select an option to specify an action when user clicks a button:

- **Stop task**
- **Assign variable**

Stop Task On

Select an option to specify when the task stops when the user clicks a button on the message box:

- **Cancel/No**
- **OK/Yes**

Auto Choice

Click an option to specify when the task continue or stops if a user does not select a button on

the message box.

- **None**
- **Cancel/No**
- **OK/Yes**

After ____ Sec.

Enter the number of seconds to wait before implementing the button that you selected in the **Auto Choice** area.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

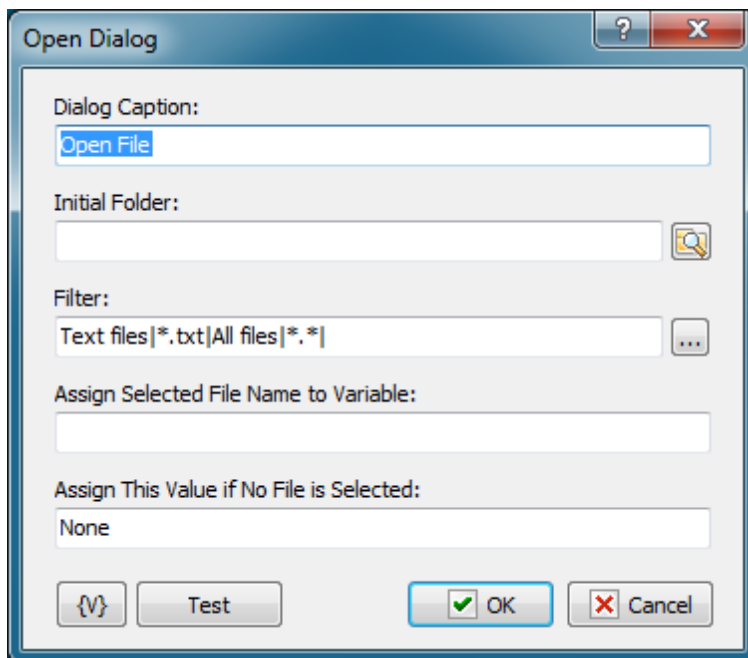

Test

Click this button to ensure that the parameters for the current action work.

4.2.3 Open Dialog

Displays a dialog box that allows you to open file. You can set the title of the dialog box, the initial folder, and the type of files a user can open.

For example, you can use this action in a task in which you might want to select file for uploading to FTP server.

Dialog Caption

Enter the caption of the dialog box. For example, you could enter a caption "Open Log Files" for the dialog box.

Initial Folder

Set the folder that you want as the starting folder for the dialog box. For example, you could enter "My Documents" or "Daily Backups." Click the browse button to select a folder.

Filter

Enter the criteria for including file types that you want the dialog box to open. These types appear in options for opening files on the dialog box, such as **Files of Type**. Click the ... button to add types with the **Filter Editor** dialog box. You can click a field in this dialog box and add file type extensions and a name for the file type.

Assign Selected File Name to Variable

Enter a variable name to store the selected file name to; for use in other actions of task.

Assign This Value if No File Selected

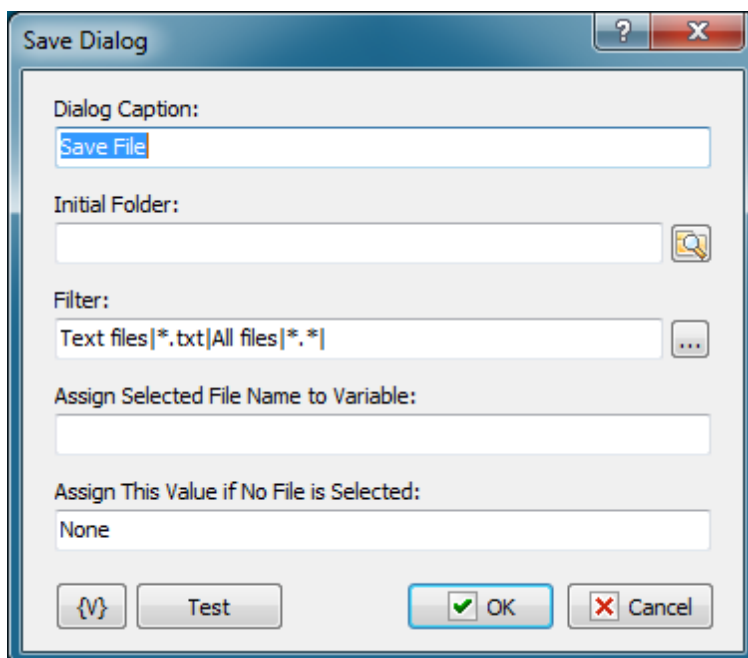

Assign a value to store if no file is selected, i.e. the **Cancel** button was clicked.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.4 Save Dialog

Opens a dialog box that allows users to save a file. You can specify the title of the dialog box, the start folder, and which types of files a user can save. For example, you might want to use this action that copies a file and you want to specify where to copy the file.

Dialog Caption

Enter the caption of the dialog box. For example, you could enter a caption "Save Log Files" for the dialog box.

Initial Folder

Set the folder that you want as the starting folder for the dialog box. For example, you could enter "My Documents" or "Daily Backups." Click the browse button to select a folder.

Filter

Enter the criteria for including file types that you want the dialog box to save. These types appear in options on the dialog box, such as **Files of Type**. Click the ... button to add types with the **Filter Editor** dialog box. You can click a field in this dialog box and add file type extensions and a name for the file type.

Assign Selected File Name to Variable

Enter a variable name to store the selected file name to; for use in other actions of task.

Assign This Value if No File Selected

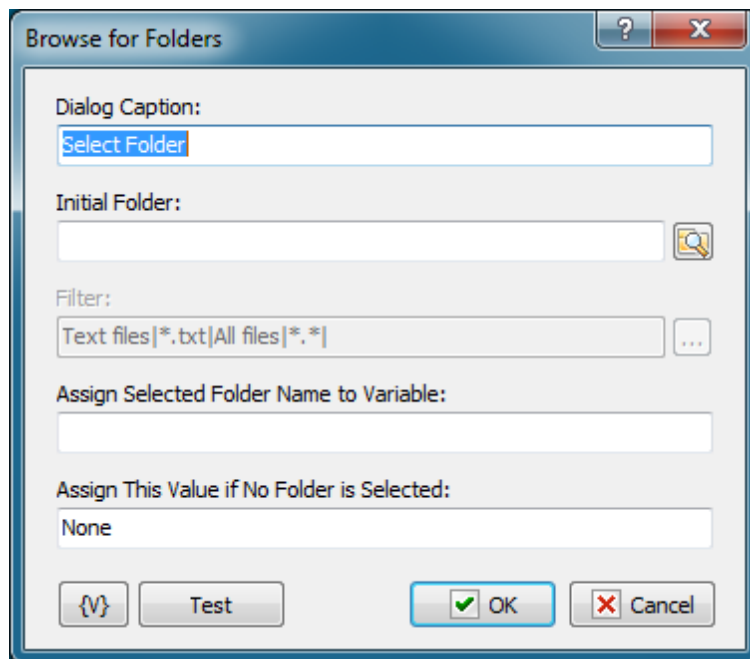

Assign a value to store if no file is selected, i.e. the **Cancel** button was clicked.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.5 Browse for Folders

Displays a dialog box that allows users to browse folders on a local or remote drives. You can set the title of the dialog box, the start folder, and what type of files a user can select. For example, if you create a task that downloads files from Internet, you can display this dialog box so you can select where to save the downloaded files.

Dialog Caption

Enter the caption of the dialog box. For example, you could enter a caption "Select Destination Folder" for the dialog box.

Initial Folder

Set the folder that you want as the starting folder for the dialog box. For example, you could enter "My Documents" or "Daily Backups." Click the browse button to select a folder.

Filter

This option is not available for this action.

Assign Selected Folder Name to Variable

Enter a value to store the selected file name in a variable expression for use in other actions or tasks.

Assign This Value if No Folder Selected

Assign a value to store if no folder is selected, i.e. the **Cancel** button was clicked.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.6 Browse for Computers

Displays a dialog box that allows a user to select computers on the local network. You can set the title of the dialog box and other settings. For example, in a task that sends a network

message, you can select a computer to send a message to.

Dialog Caption

Enter the caption of the dialog box. For example, you could enter a caption "Browse Backup Server" for the dialog box.

Initial Folder

This option is not available for the **Browse for Computers** action.

Filter

This option is not available for the **Browse for Computers** action.

Assign Selected Computer Name to Variable

Enter a variable name to store the selected computer name to; for use in other actions of task.

Assign This Value if No Computer Selected

Assign a default value to store if no computer is selected.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.7 Input Box

Displays an input dialog box that lets the user enter a string and assigns the entered value to a specified variable.

**Prompt String**

Specify the text that prompts the user to enter input in the edit box.

Assign Entered Value to Variable

Enter a variable name to store the entered value to; for use in other actions of task.

Assign this Value, if Cancel Pressed

Assign a default value to store if Cancel is pressed.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Test

Click this button to ensure that the parameters for the current action work.

4.2.8 Show Notification

This action is for displaying different popup messages on a screen. These messages do not demand any interactive action (e.g. pressing the key OK). The message closes automatically in several seconds after its displayed. The message can be displayed in two ways:

- As a tray icon balloon
- As popup windows in the corner of the screen

You can press the button Test in the editor of action parameters and then watch how your message looks with the specified parameters.

General

The screenshot shows a 'Show Notification' dialog box with the following fields and controls:

- Title:** A text input field.
- Message:** A text input field.
- Icon kind:** A dropdown menu currently showing 'Default'.
- Notification kind:** A dropdown menu currently showing 'Desktop Alert'.
- Duration:** A spinner box set to '5' followed by the text 'seconds'.
- Buttons:** '{V}', 'Test', 'OK', and 'Cancel'.

Title

The title of a message. The usage of variables is allowed.

Message

The body of a message. The usage of variables is allowed.

Icon kind

Select a message icon. Available variants are:

- Information
- Exclamation
- Error
- Default

Alert Kind

Select the kind of a message:

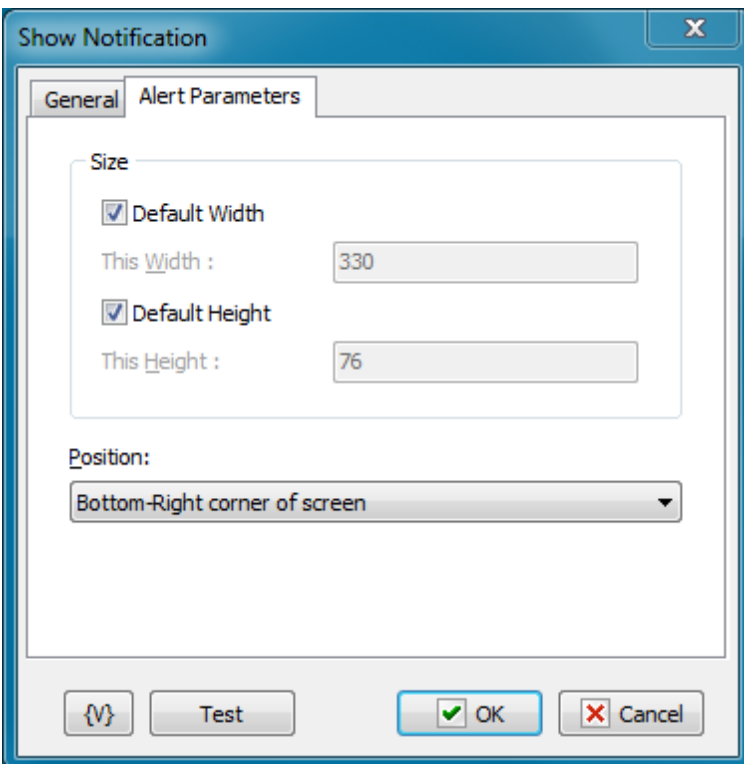

- **Desktop Alert** – a message as a popup window in a screen corner. If the RoboTask sends several messages in succession, all of them will be displayed one above another.
- **Tray Icon Balloon** – the display of the message as a standard system balloon. If the RoboTask sends several messages running, then only the last message will be displayed on the screen. Every next message will overlay the previous one.

Duration

The duration of a message display. At the end of this time, the message disappears from the screen automatically. It is possible to change the duration of the message from 2 to 20 seconds. By default, it is 5 seconds.

Alert Parameters

Additional parameters, available for the message display mode "Desktop Alert" only.

Width

The width of the message window. On default, it is 330 pixels. This is enough for the majority of short messages. When specifying the width of the window the usage of variables is allowed.

Height

The height of the message window. On default, it is 76 pixels. This is enough for the majority of short messages. When specifying the height of the window the usage of variables is allowed.

Position

Select one of the four screen corners where the message will appear. On default, it is the right lower screen corner, i.e. where the system tray is.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must

place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.2.9 Choice Dialog

The Choose Dialog is necessary to select one value of several alternatives. The action saves the number of chosen alternative (beginning from 1) into a variable. Then it is possible to do actions according to a choice.

If a user rejects a choice (that is, the button *Cancel* is pressed), the value of the choice is 0.

Dialog Title

Specify a title for a choice menu.

Items

A list of menu items for a choice. The list can be edited with buttons *Add*, *Edit*, *Delete*. Also it is possible to change the order of options using buttons *Move Up* and *Move Down*.

Save Selected Item Number to Variable

Specify the name of a variable into which is necessary to save the choice result. If one of items is chosen, the number of the item will be saved beginning from 1.

If the button *Cancel* is pressed, then 0 will be saved.

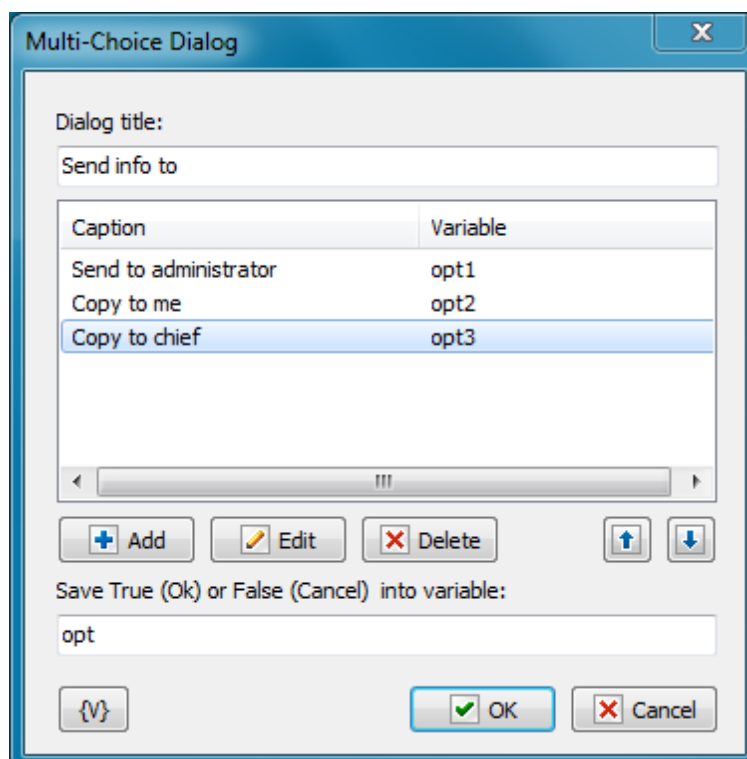

4.2.10 Multichoice Dialog

The Multi Choice Dialog allows to switch on or off each option of the proposed set.

For example, a task collects certain information and allows to pass the information to several workers:

- Send the Message to Mike;
- Send the Message to administrator;
- Copy Message to Boss.

The Multi Choice Dialog allows to select alternatives in any combination. The RoboTask saves the values of a choice into separate variables for each option (True or False)

Dialog Title

Specify the title for a choice menu.

Items

The list of menu items for a choice. Each item is related to a variable into which the value of a choice of the item is saved. True or False.

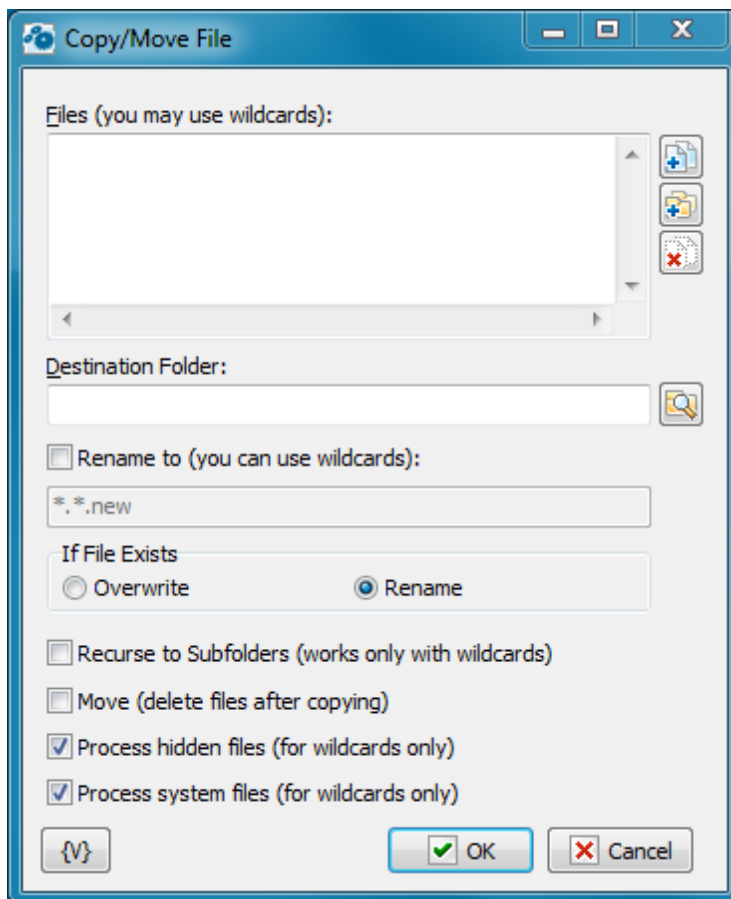

Save True (OK) or False (Cancel) into Variable:

Specify the variable into which it is necessary to save the work result of dialog. If a choice is made, the value True is saved. If not (that is, the button Cancel is pressed), the value False is saved.

4.3 Files and Folders

4.3.1 Copy/Move File

Copies or moves one or more files that you specify. You can set the source and the destination. Wildcards are allowed. For example, you can use this action to copy backup archives from your computer to another computer on the network.

Files

Enter the files you want to copy or move. Wildcards are allowed. Use the Plus buttons to add files to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Destination Folder

Enter the folder to which you want to move or copy the files. You can click the browse button to find folders.

Rename to (you can use wildcards)

If you want to change the original name of file you should turn on this checkbox and specify new file name or the mask of new name in the field below. This option allows you to copy the file to new filename in the same folder.

If File Exists

Specify the action to take if a file already exists in the destination location.

- **Overwrite** - replaces the destination file with the file you are copying or moving.
- **Rename** - renames the source file when you copy or move it to the new location.

Recurse to Subfolders

Copies or moves all the files in the subfolders of the current directory.

Move

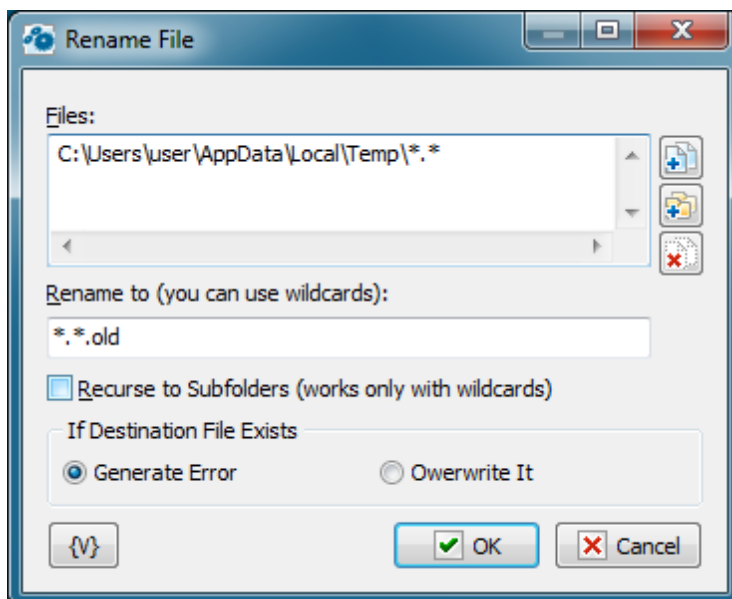

Deletes the original files after you copy or move them to a new location.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.2 Rename File

Renames one or more specified files. Wildcards are allowed. For example, you can copy the files to another folder and automatically rename them using this action.

Files

Enter the files you want to rename. Use the Plus buttons to add files or folders to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Rename To

Enter the name or partial name for the new filename. You can use a wildcard if you want to rename part of the filename.

Recurse to Subfolders

Renames the files in the subfolders of the current directory.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.3 Delete File

Deletes one or more files you specify. Wildcards are allowed. For example, you can use this action to automatically delete cookies from your Internet cache every day to protect your privacy and computer security.

Files

Enter the files you want to delete. Use the Plus buttons to add files or folders to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Delete to Recycle Bin

Moves files to the Windows Recycle Bin. Use this flag to prevent possible data loss.

Recurse to subfolders

Deletes the files in the subfolders of the current directory.

Delete Folders

Removes the subfolders. This option works only with wildcards.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must

place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.4 Write Text File

Creates a text file with the specified text. For example, you can write a text file listing which user is logged into a computer at a particular time.

Text File

Enter the name of the text file to save. You can click the browse button to select a file.

Text

Enter the text that you want saved in the file.

Text Encoding

The action can provide the following coding:

- ANSI text
- UTF-8 text
- Unicode text

If File Exists

Specify the action to take if a file already exists in the destination location.

- **Overwrite** - replaces the destination file with the new file.
- **Append** - append specified text at the end of existing text file.

Suppress Trailing End-Of-Line symbols

If you want to remove trailing EOL symbols switch on this checkbox.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.5 Search for Files

Looks for files and creates a file list. This action is useful with pre-defined variables, such as % TextFile(file_name)%. You can create a file list, such as a list of all .Png files, and then use this in a list of actions, such as copying, moving, or deleting files.

General tab

Search for Files

Enter the file path with file mask that you want to search for. Use the Plus buttons to add files or folders to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Exclude Masks (Comma Separated)

Enter one or more file masks separated with commas that you do not want to search.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- ***.txt** - all the files with the .txt extension.
- **mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- ***.tmp, *.\$\$\$, *.bak** - all the files with the .tmp, .\$\$\$ and .bak extensions.
- **{bakext}** - file mask(s) from the {bakext} variable.

Recurse to Subfolders

Searches the files in the subfolders of the specified folder.

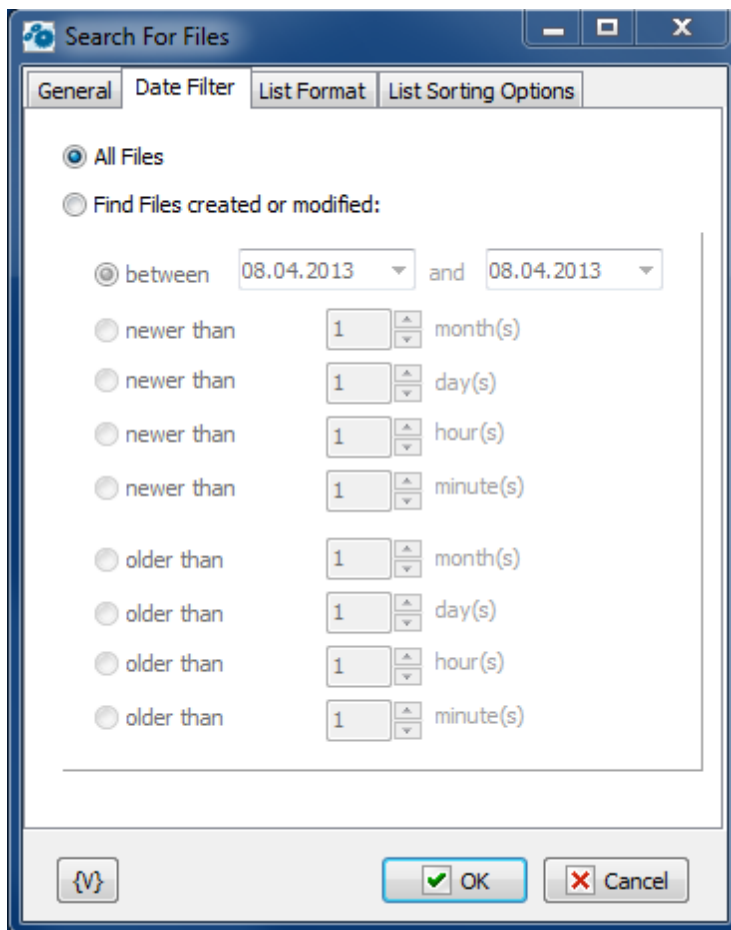

Save File List To

Enter a path and name for a file that contains a list of the files that were searched. Click the **List Format** tab to set other options for this list.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Date Filter tab

All Files

Select this option to search all files.

Find Files Created or Modified

Click this option to search files according to one of the following criteria:

- **Between**
- **Newer Than ___ Months**
- **Newer Than ___ Days**

- Older Than ____ Months
- Older Than ____ Days

List Format tab

Without Path Name

Lists files without the path names (i.e. file names only).

Insert Text Before

You can specify a text that will be inserted at the beginning of the list file.

Insert Text After

You can specify a text that will be inserted at the end of the list file.

Insert Text Before Each Line

You can specify a text that will be inserted at the beginning of each line.

Insert Text After Each Line

You can specify a text that will be inserted at the end of each line.

List Sorting options

Parameters of internal sorting of the file list

Sort the list of filenames

Turn on the checkbox if you want to sort the list

How to sort

There are four sorting modes:

- By file name
- By file time
- By file size
- By depth of nested folders

Sort order

There are two modes: ascending or descending ordering

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.6 Change Folder

Allows you to change the current folder. This is useful if you need to set the current folder during a series of actions or tasks. This action is useful with other file actions like copy, move.

Folder Name

Enter the name of the destination folder. You can click the browse button to select a folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.7 Create Folder

Makes a new folder on a local or remote drive. For example, you could automatically create a new folder for your backups based on the current date.

New Folder Name

Enter the name for the new folder. You can click the browse button to select a folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.8 Rename Folder

Renames an existing folder. For example, if you have copied a folder with files, you can rename the original folder.

Old Folder Name

Enter the original name of the folder. You can click the browse button to select a folder.

New Folder Name

Enter the new name for the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in an edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.9 Remove Folder

Deletes an existing folder. For example, if you have archived your company financial reports every week for the past year, you can create a task that automatically deletes folders that are more than a year old.

Folder Name

Enter the name of the folder that will be removed.

Remove Folder if It's Not Empty

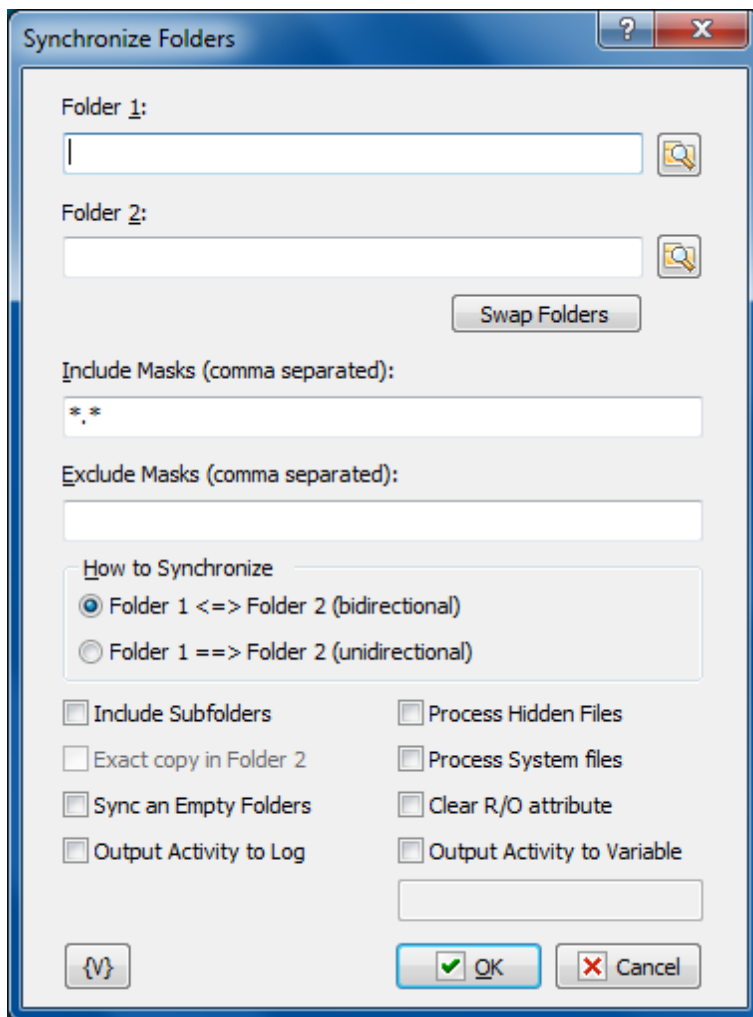

If this option is selected, the specified folder will be deleted even if it is not empty (i.e. contains files and subfolders), otherwise the specified folder will be deleted only if it is not empty (i.e. does not contain files and subfolders).

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in an edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.10 Synchronize Folders

Synchronizes the two folders that you specify. The synchronization method may be bi-directional or uni-directional. For example, if you travel a lot, you might want to create a task that synchronizes data in a folder on your laptop computer and a folder on your desktop computer.

**Folder 1**

Enter the first folder that you want to synchronize. You can click the browse button to select a folder.

Folder 2

Enter the second folder that you want to synchronize.

Swap Folders

Click to place the folder listed in **Folder 2** in the **Folder 1** box and the folder in **Folder 1** in the **Folder 2** box.

Include Masks (Comma Separated)

Enter one or more masks separated with commas to specify which files to synchronize, such as *.exe, *.cnt, *.hlp. The default wildcard mask "*. *" means that all folders and files are synchronized. You can specify one or more masks separated by commas.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- ***.txt** - all the files with the .txt extension.
- **mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.

- ***.tmp, *.\$\$\$, *.bak** - all the files with the .tmp, .\$\$\$ and .bak extensions.
- **{bakext}** - file mask(s) from the {bakext} variable.

Exclude Masks

Enter one or more masks separated with commas to specify which files to skip in the synchronization. You can specify one or more masks separated by commas; for example, *.bak, *.old, *.\$\$\$.

How to Synchronize

Select one of the following options:

- **Folder 1 <=> Folder 2 (Bi-directional)** - new or newer files that are available in Folder 1 are copied to Folder 1, and vice versa.
- **Folder 1 ==> Folder 2 (Uni-directional)** - only new or newer files that are available in the Folder 1 are copied to Folder 2; the contents of Folder 2 does not affect the contents of Folder 1.

Include Subfolders

Click this check box to synchronize all files in the subfolders.

Exact Copy in Folder 2

Available only with unidirectional synchronization when you select **Folder 1 ==> Folder 2**. This option ensures that files that are available in Folder 2, but not in Folder 1, are deleted.

Sync an Empty Folders

If this checkbox is switched on, the action copies the structure of empty folders. Otherwise, only files will be synchronized.

Output Activity to Log

If you want to write the log of synchronization into the task log, switch on this checkbox. The action will put the information about copied and removed files into the task log.

Output Activity to variable

If you want to write the log of synchronization into a variable, switch on this checkbox and put the variable name in the field. The action will put the information about copied and removed files into the log.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.11 Wait for file

Pauses the task and waits until the selected file will be available. After the monitored file is been available, the task is resumed. If the specified file is not opened in another process at the moment when the action is due, the task is not paused.

**Wait for file**

You can either select the file name or type its name manually.

Waiting

This parameter defines the timeout in seconds to wait until the process is finished. You can also specify an infinite timeout.

If the timeout is over, but the process is not finished, the action will generate the following error: Timeout is over.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.12 SortText

This action is used to sort strings in a text or in a text file in the ascending or descending order. It is possible to assign the sorted text to a variable for further processing (e.g. in "Text Loop") or save it to a file. You can specify the source text explicitly using variables or read it from an external file.

Source

You can select the source for the source text in this group of parameters: specify an external file or specify the text explicitly.

File Name – specify the full file name either manually or using the Open File dialog box by clicking the button to the right from the field. It is possible to use RoboTask variables.

This text – if you want to specify the text explicitly, fill the text field manually. It is possible to use variables in the text. RoboTask will replace them with variable values during the action.

Sort Mode

You can specify the string sorting mode in this group

- Ascending or Descending
- Case Sensitive
- Remove duplicates - this allows to keep only unique lines in the text.

Destination

Select at least one of the variants (or both at once) :

Assign text to Variable – specify the name of the custom variable the sorted text will be assigned to. It is impossible to use variables.

Save text to File – specify the full file name either manually or using the Open File dialog

box. It is possible to use RoboTask variables.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.13 Unique File Name

The action generates unique file name in specified folder by the mask. Sometimes it's necessary to create the file with unique name where you need to store some temporary data. Next, the file name have to be saved into variable.

Folder Name

Specify the folder where you want to create the file. You can click the browse button to select a folder. The using of variables are allowed.

File Mask

It is the ordinary file mask with using characters "*" and "?". Action replaces "*" with 8 random characters and "?" with single random character.

You have to specify the mask of file name only. The path portion of the file name will be ignored. The using of variables are allowed.

For example:

```
tmp*.txt
{Hours}{Minutes}-*.dat
FileList-???.txt
```

Save File Name to Variable

Enter the variable name. The action saves new file name into this variable. The using of variables is unacceptable.

Without Path

If you want to save the file name only without path, check this checkbox.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.3.14 File Attributes

Sometimes you need to change file attributes in file operations. As a rule, the ReadOnly attribute inconveniences most of all. This action serves for changing of file attributes.

File or Folder name

Specify the name of a file or a folder. You can use buttons on the right of an edit field. A file mask is inadmissible; that is, the action can process only the specified file.

You can use variables.

Attributes

Specify the attributes, which you want to set or to remove. This action can control 4 attributes:

- Archive
- Hidden
- Read Only
- System

Please, notice that Checkboxes have three positions:

- **Switched on** – this means that you want to set an attribute
- **Switched off** – this means that you want to remove an attribute
- **Grayed, or intermediate state** – this means that you want to leave this attribute without changing.

By default, all the checkboxes are in Grayed state.

4.3.15 File Date and Time

This action is for changing date and time of files or folders. Date and time are specified as a line. The format has to correspond to the regional settings of your computer. To check the date format it is enough to find out what the form which the variable **{DateTime}** returns. If the date and time are specified incorrectly, you will get run-time error.

File and Folder Names

Enumerate file names, one name per line. The usage of a file mask is allowed (for example, `c:\incoming*.txt`). It is also allowed to use variables when the file name is formed.

Set This Date and Time

Specify the date and the time which are necessary to assign to the files. The date and the time are specified as string. The format has to correspond to the regional settings of your computer. The usage of variables is allowed.

Process Files

Switch on this checkbox if you want to process the files corresponding to the list.

Process Folders

Switch on this checkbox if you want to process the folders corresponding to the list.

At least one of two options "Process Files" or "Process Folders" has to be on. It is possible to switch on both options at the same time.

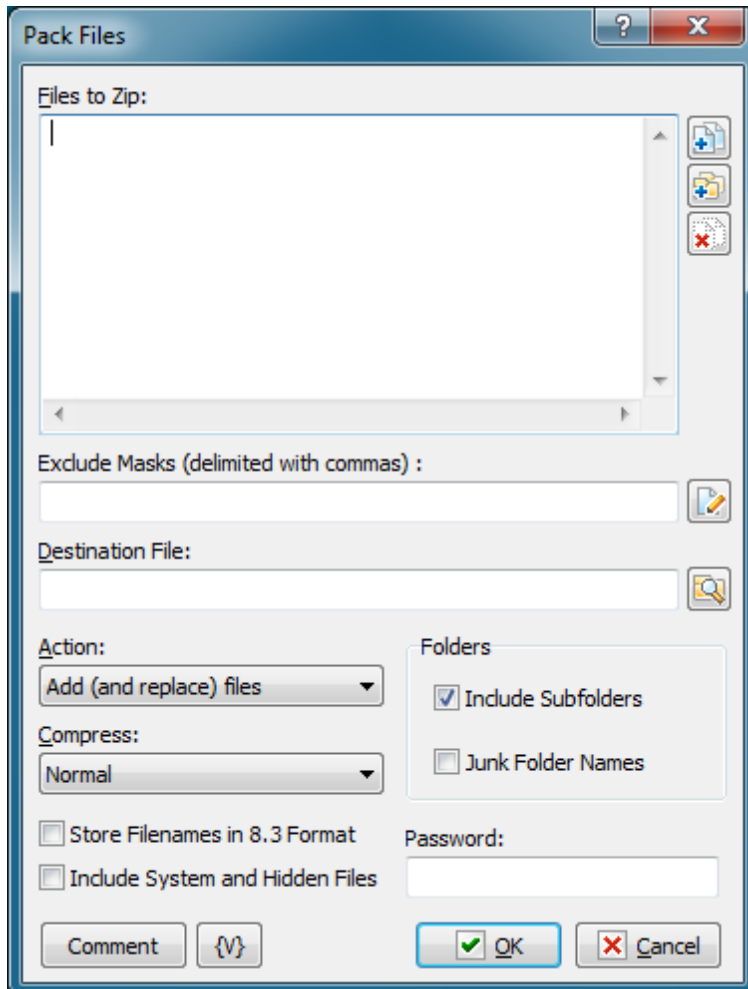

4.3.16 Empty Recycle Bin

This action empties a recycle bin of a user on all hard disks. The action does not required any additional settings.

4.4 Zip

4.4.1 Pack Files

Creates and adds files to zip files. You can use this action to back up your files. For example, you can use this action to create a task that automatically zips weekly status reports files so that they can be copied to the central server for company summary reports every month.

Files to Zip

Enter the files you want to add to a zip file. Wildcards are allowed. Use the Plus buttons to add files or folders to the list. To clear the list, click the X button.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Destination File

Enter the filename for the resulting .zip archive.

Action

Select one of the following actions for creating or adding to the zip file:

- **Add and replace files** - add all files to the archive.
- **Freshen existing files** - add only changed files to the archive.
- **Move files** - add files to the archive and remove them from the local folder.
- **Update and add files** - add only changed or new files to the archive.

Compress

Select one of the items on the dropdown list to determine the level of compression, or size, of the archive file:

- **Maximum** - creates the smallest zip file possible, while requiring the most time to create the archive.
- **Normal** - creates a slightly compressed zip file taking the usual amount of time to create the zip file.
- **Fast** - produces slightly less compression than **Normal**.
- **Super Fast** - produces an archive with even less compression than **Fast** and **Normal**.
- **None** - produces an archive file that is not compressed. This level of compression is the fastest.

Folders

Include Subfolders

Click this check box to include the subfolders in the archive. Files are archived with the paths stored in the archive file.

Junk Folder Names

Does not include folder paths in the archive file. For example, if you add C:\documents*.doc, the .doc files are included into the root folder of the zip archive.

Store Filenames in 8.3 Format

Ensures that filenames are stored with the 8.3 name format, such as foo_mon.txt, especially important for FAT file systems.

Include System and Hidden Files

Archives system and hidden files in the zip file.

Password

Enter a password that is required to unzip the archive, if you want to protect the file.

Comment

Enter a memo note for the zip file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.4.2 Extract Files

Extracts files from an existing ZIP file to the folder that you specify. For example, you can create a task that automatically unzips files when you download .zip files to your hard drive.

File to Unzip

Enter the name of the zip file to extract files from.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- *.txt - all the files with the .txt extension.
- mydoc?.doc - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- *.tmp, *.\$\$\$, *.bak - all the files with the .tmp, .\$\$\$ and .bak extensions.
- {bakext} - file mask(s) from the {bakext} variable.

Destination Folder

Enter the destination folder where you want to extract files.

Files to Extract

Enter the names of the files to unzip from the zip file, separated by commas. If left blank, all files are unzipped.

Overwrite Existing Files

Click to allow the extracted files to overwrite existing files with the same name.

Skip Older Files

Click to ensure the files in the zip archive are not extracted if they are older than the existing files on the local computer.

Use Folder Names

Click this check box to extract files and the directory paths that are archived in the zip file. For example, if a file is zipped with the path `\temp\foo.txt`, a `\temp` folder is created in the local directory and the `foo.txt` file is unzipped to that folder.

Password

Enter the password for the zip file, if the zip file is password-protected.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the `{V}` button.

4.5 Internet

4.5.1 Check for Email

Checks to see if email exists on a POP3 server that you specify. For example, you can create a task that checks e-mail in the morning and the evening automatically for you, thus minimizing distractions during your work day.

The screenshot shows a dialog box titled "Check For Email". It contains the following fields and options:

- POP3 server: [text input field]
- Port: [spin box with value 110] [checkbox Use SSL]
- Username: [text input field]
- Password: [text input field]
- Action: Stop task Assign variable
- Stop this Task if: Mail is waiting Mail is NOT waiting
- Buttons: [OK] [Cancel]

POP3 Server

Enter the POP3 server for e-mail.

Port

Enter the port number. The default port number is 110.

Use SSL

Select this checkbox if you want to use SSL connection.

Username

Enter the user name for the e-mail account on the mail server.

Password

Enter the password for the e-mail account.

Stop this Task if

Enter whether you want the current task to do one of the following before e-mail is downloaded from the mail server:

- **Mail is Waiting** - stops the task if mail is on the mail server.
- **Mail is Not Waiting** - stops the task if mail is not on the mail server.

4.5.2 Send Email

Sends email through the specified SMTP server. Messages can have attachment files. For example, you can create a task that automatically e-mails monthly invoices to a specific customer outlining the sales charges for that month.

Message tab

Send Email

Message SMTP Server & Mail agent

From: user@host.com

To:

CC:

BCC:

Subj: Enter subject

Request a Return Receipt

Encoding: Western European (ISO)

Message text: Is HTML

Enter message body

Attachments:

{?} OK Cancel

From

Enter the e-mail address of the person sending the e-mail.

To

Enter the e-mail address to which you are sending the e-mail.

CC

Enter the address of any people to which you want to send a courtesy copy.

Subj

Enter the subject of the e-mail.

Request a Return Receipt

If you want to get a confirmation of a reading, switch on this checkbox. Pay attention, it does not guarantee getting a receipt even if an addressee has opened and read the letter. It depends on settings of a mail client of the addressee.

Encoding

The character set of the message. RoboTask doesn't convert specified text of the message,

but you have to specify character set if the message contains non-latin characters.

Message Text

Enter the text that you want to send. If you enter .html tags, click the **Is HTML** check box.

Tip

- You can cut and paste .html code from Notepad into this window with the CTRL+V keys.

Is HTML

Click this check box if you have entered .html tags in the **Message Text** box.

Attachments

Click the plus button to add attachments to the e-mail. You can add more than one attachment. Click the X button to remove attachments from the list.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

SMTP Server tab

The screenshot shows a dialog box titled "Send Email" with two tabs: "Message" and "SMTP Server & Mail agent". The "SMTP Server & Mail agent" tab is active. It contains the following fields and options:

- Host:** An empty text input field.
- Port:** A text input field containing the number "25".
- SSL/TLS mode:** A group box containing three radio buttons: "None" (selected), "SSL", and "TLS".
- Authentication Required:** A checkbox that is currently unchecked.
- User Name:** An empty text input field.
- Password:** A dropdown menu currently set to "Explicit password", with an empty text input field below it.
- Mail agent:** A text input field containing the text "RoboTask".

At the bottom of the dialog box, there are three buttons: a help button (represented by a question mark icon), an "OK" button with a green checkmark icon, and a "Cancel" button with a red X icon.

Host

Enter the name of the host to which you want to send the e-mail using SMTP (simple mail transfer protocol).

Port

Enter the port number to use.

SSL/TLS mode

You can set SSL/TLS mode of the connection. There are three options:

- None
- SSL
- TLS

Authentication Required

Click this check box if the remote mail server requires user authentication and enter the user name and password to log into the remote server.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must

place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.5.3 Download Files

Downloads one or more files through the Internet from specific Web or FTP sites. For example, if you are participating in a beta test program for new software, you can automatically download updates to the beta software on a daily basis so that you stay up-to-date.

Important

- Wildcards are not supported.

Files to Download

Enter the http, https or ftp URLs that you want to download.

Save in Folder

Enter the path of the folder in which you want to save the files.

If File Exists

Click an option to determine whether to overwrite existing files with the downloaded file or rename the downloaded file.

- **Rename**
- **Overwrite**

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.5.4 Ping Host

Allows you to send a ping message to a host. This action sends Internet Control Message Protocol (ICMP) Echo Request messages to verify IP-level connectivity to another TCP/IP computer. The action receives a receipt of corresponding Echo Reply messages, along with the round-trip times. **Ping Host** is based on the Ping command, the primary TCP/IP command used to troubleshoot connectivity, reachability, and name resolution.

For example, in a backup task, you can use this action to check to see if a host is up before you start a process to copy files to that host.

Host Name

Enter the name or IP address of the host.

Timeout (Msec)

Indicates the amount of time, in milliseconds, for the action to wait for the Echo Reply message that corresponds to a given Echo Request message to be received. If the Echo Reply message is not received within the time-out, the "Request timed out" error message is displayed.

Assign Reply Time to Variable (Msec)

Enter a variable name for the reply time that you want to assign to.

Assign This Value if Host Does Not Respond

Enter a value to assign if the host does not respond to the Ping message.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.5.5 Check HTTP address

This action is for checking the Web URL and receiving the captions of the response to analyze. The action works according to the **HTTP** and **HTTPS** protocols.

General tab

The screenshot shows a dialog box titled "Check HTTP Address" with three tabs: "General", "Request Headers", and "Response Headers". The "General" tab is active. It contains the following fields and options:

- URL:** A text input field.
- Handle Redirections**
- Referrer:** A text input field.
- Save HTTP Result to Variable:** A checked checkbox with an associated empty text input field below it.
- Save Raw Response Headers to Variable:** An unchecked checkbox with an associated empty text input field below it.

At the bottom of the dialog, there is a button with curly braces {}, and two buttons labeled "OK" (with a green checkmark) and "Cancel" (with a red X).

URL

Specify the HTTP address of the checked click link. For example: *http://www.robotask.com/*

You can specify addresses with parameters: *http://www.robotask.com/forum/viewtopic.php?f=4&t=1441*

It is also allowed the usage of the Secure HTTP (HTTPS) addresses. For example: *https://www.google.com/search?q=robotask*

The address must begin from the **http://** or **https://**

Handle redirections

Switch on this option if you want the action to process the redirection of the query automatically. But you should remember that you will get the response from the final URL.

Referrer

Specify a referrer for a query. Referrer is the URL from which this HTTP query was performed. Many sites use this parameter of query to form a response.

Save HTTP Result into Variable

If you need to save the HTTP result into a variable, switch on this checkbox and input the variable name. HTTP result is a number. For example:

- 200 – OK
- 403 Forbidden
- 404 – page not found
- etc.

You can read more about HTTP results here:

<http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html>

Save Raw Response Headers into Variable

To save all captions of the response into a variable, switch on this checkbox and input the variable name.

Request headers

You can define the user captions of the request on this tab. You can add captions on a list, edit or remove the selected caption.

Response headers

If you need to save values of certain captions into variables, you should use this tab.

To add a caption on a list, it is necessary to specify the caption of the response and the name of the variable into which you need to save the value of the caption. If the specified caption does not exist, the action saves empty value.

4.5.6 Wake On LAN

The action permits to "wake up" another computer by means of sending the special signal through a net. You can read about this technology here in detail: <https://en.wikipedia.org/wiki/Wake-on-LAN>. To have the computer awoken, this function should be permitted in the setting BIOS of the computer. As a rule, this function is permitted on default.

The function Wake-on-LAN works stably for stationary (desktop) computers with wire connection to network. The Wake-On-LAN permit to "wake up" a computer out of any status: sleep, hibernate and even switched off. The necessary condition is that the computer should be connected to a power supply (an outlet) and have physical connection to a network.

The possibility of awakening for laptop depends on the manufacturer and the model of computer and perhaps it depend on the observance certain condition. For example, in our tests it is necessary that the lid of the laptop was opened and the computer was connected to its power module.

Host

The name of the computer or an IP address. You can specify both an exact address (for example, 192.168.1.36) and a broadcast address (for example, 192.168.1.255).

In the mode of one segment of a local network it is permitted even not to specify any exact address of a sub-network and to do a broadcast request to all computers of the segment (for example, 255.255.255.255).

Port

The port of recipient. On default, it is 9. You can specify any port if you use the local network without firewall. If a target computer is in a segment of the network closed with firewall, you should tune a port forwarding to the signal can get the target.

MAC address

This is a hardware address of a network interface (a physical address). To retrieve it, it is necessary to specify the command in the command line:

```
ipconfig /all
```

You can see a MAC address through the control panel:

Control Panel -> Network and Sharing Center

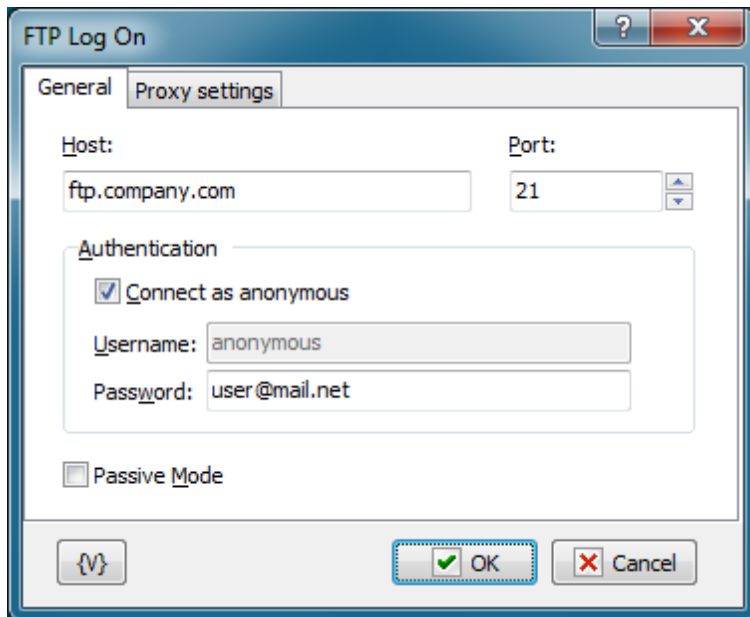

Then, you should click the link *Local Area Connection* (or another connection) and open the window "Details".

MAC address is important parameter. The function Wake-On-LAN works only if the specified address coincides with a hardware one. Otherwise, the target computer just ignores the command. Therefore, in the local network it is possibly only to send a broadcast request, because the computer reacts only when MAC address coincides. The rest of computers of the segment just ignore the request.

4.6 FTP

4.6.1 FTP Log On

Allows you to log on to an Ftp site, or remote server. For example, you can create a task to automatically Ftp updated daily reports from a co-worker's computer every day.

**Host**

Enter the name of the remote host that you want to log into.

Port

Enter the number of the port that you want to use. The default port is 21.

Authentication**Connect as Anonymous**

Click this check box if the remote server allows anonymous logins.

Username

Enter the name of the log in account.

Password

Enter the password of the log in account.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.2 FTP Log Off

Allows you to log off an Ftp site, or remote server. No specific settings are associated with this action. For example, when you work from home, you can create a task that Ftps daily files that you have worked on to a remote server in your company's network to protect your data.

4.6.3 FTP Download

Copies remote files to the local computer using the current file transfer type. For example, if you are participating in a software beta program, you can download daily updates automatically to stay up-to-date.

Tip

- Click the **{V}** button to insert a variable that holds the name of the local file or the remote folder.

Remote File

Enter the name of the remote file that you want to copy to the local computer.

Local Folder

Enter the path and name of the local directory to which you want to copy the remote file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the **{V}** button.

4.6.4 FTP Upload

Allows you to place files on an Ftp site. For example, if you must post daily updated financial reports to a web site, you can create a task to automatically upload the updated reports to the company web site at the end of each day.

**Tip**

- Click the **{V}** button to insert a variable that holds the name of the local file or the remote folder.

Local File

Enter the name of the local file that you want to copy to the remote server.

Remote Folder

Enter the path and name of the directory on the remote server.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the **{V}** button.

4.6.5 FTP Rename File

Allows you to change the name of files on a remote server. For example, in an FTP session, you can use this action to rename files that you might accidentally overwrite on the remote server with updated files.

**Tip**

- Click the **{V}** button to insert a variable that holds the new file name or the old file name.

Old File Name

Enter the name of the file that you want to rename.

New File Name

Enter the name that you want to give the file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.6 FTP Delete File

Allows you to remove files from a remote server. For example, you can use this action to remove old backup files on the remote server that are no longer needed.

Remote File

Enter the path and file name that you want to delete on the remote server. Click the {V} button to insert a variable that holds the path and name of the file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.7 FTP Change Folder

Allows you to switch the current folder on a remote server. For example, during an FTP task that backs up your files, you can use this action to copy files to different directories on the remote server.

**Remote Folder**

Enter the path or folder name on the remote server that you want to switch to. Click the **{V}** button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.8 FTP Create Folder

Allows you to create a new folder on a remote server. For example, during an FTP task, you can use this action to create a new folder based on the current date for each set of daily backup files.

**Remote Folder**

Enter the path or folder name on the remote server that you want to create. Click the **{V}** button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.9 FTP Remove Folder

Allows you to delete a folder on a remote server. For example, you can create a task to remove company reports that are more than six months old from the remote server.

Remote Folder

Enter the path or folder name on the remote server that you want to remove. Click the **{V}** button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the **{V}** button.

4.6.10 FTP PWD

Allows you to print the current directory on the remote computer. This action saves the task log to the current directory on the FTP server. Also, you can assign the current directory to a custom variable for future use.

Assign Remote Folder to Variable

If you want to assign the name of the current FTP directory to a custom variable, select this checkbox and type the name of the variable in the field below.

4.6.11 FTP Transfer Type

Sets or displays the type of file you are transferring. For example, if you are transferring Microsoft Word reports to the company server every day, you must set the transfer type to binary. The default transfer type is **binary**.

Transfer Type

Select whether you want to transfer the files as ASCII or binary during an FTP session. You should select **ASCII** when you want to transfer files that contain text strings, such as .html, .txt, or .xml. You should use **Binary** when transferring executable files, such as Office documents, .Exe files, and so forth. In binary mode, files are transferred in one-byte units.

4.6.12 FTP Command

Allows you to execute custom FTP commands.

Command

Enter the name of the command that you want to execute.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.13 FTP File Loop

Executes a series of commands on files or folders on a remote server during an FTP session.

General tab

The screenshot shows the 'FTP File Loop' dialog box with the 'General' tab selected. The dialog has three tabs: 'General', 'Date Filter', and 'Parameters of Sorting'. The 'General' tab contains the following elements:

- Loop Kind:** Two radio buttons, 'By Files Only' (selected) and 'By Folders Only'.
- Remote Folder and File Mask (e.g. download/*.zip):** A text input field.
- Include Subfolders:** A checkbox that is unchecked.
- Exclude Mask (comma separated):** A text input field.
- Save Results:** A section containing:
 - Assign File Name to Variable:** A text input field.
 - Without Full Path:** A checkbox that is unchecked.
 - Assign File Size to Variable:** A checkbox that is unchecked, with a text input field below it.
 - Assign Last Update Time to Variable:** A checkbox that is unchecked, with a text input field below it.

At the bottom of the dialog, there is a button with a curly brace symbol '{V}', and two buttons: 'OK' (with a green checkmark) and 'Cancel' (with a red X).

Loop Kind

Select the items you want to perform actions on: folders only, or files only.

Remote Folder

Enter the path or folder name on the remote server.

Save Results

Enter information about how you want to save the result of the file loop.

Assign File Name to Variable

Enter the name of the variable into which it is necessary to save the file name

Assign File Size to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the size of the file. This allows to use the file size data in other actions or tasks.

Assign Last Update Time to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the date and the time of the file. This allows to use the last update time information in other tasks or actions.

Date Filter tab

All Files

Click this option to include all files in the file loop.

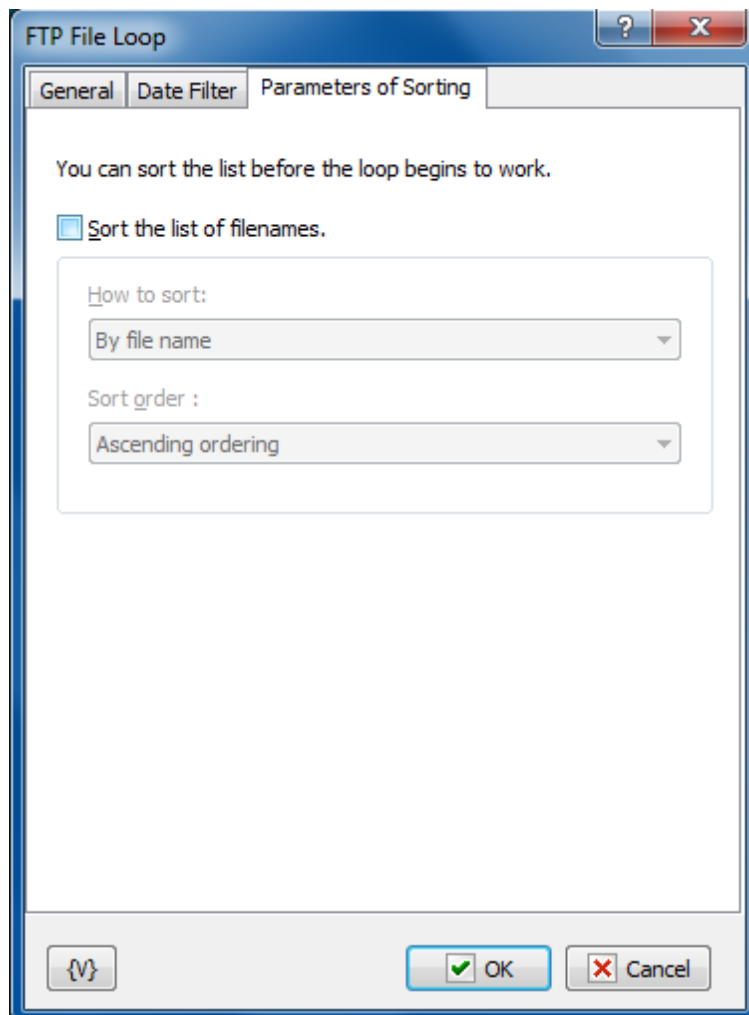

Find Files Created or Modified

Enter dates and times to include files for certain time periods in the loop.

- **Between** – You can specify two dates explicitly selecting them from a calendar. Or you can specify the expression using variables. This expression should contain the date in the format set on your computer.
- **Newer Than ___ Months**
- **Newer Than ___ Days**
- **Newer Than ___ Minutes**
- **Older Than ___ Months**
- **Older Than ___ Days**
- **Older Than ___ Minutes**

Sorting parameters

Parameters of internal sorting of the file list

Sort the list of filenames

Turn on the checkbox if you want to sort the list

How to sort

There are four sorting modes:

- By file name
- By file time
- By file size
- By depth of nested folders

Sort order

There are two modes: ascending or descending ordering

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.6.14 FTP Synchronization

Synchronizes files between a local folder and a remote folder on the FTP server. This high-level operation is very similar to "Synchronize folders", but there are several important differences:

- The time when a file is created on the FTP server is determined with the accuracy of one minute. So, if the difference in the versions of a file is several seconds, no file exchange will take place.
- Some FTP servers do not support time zones. In this case, the time when a file was created (last modified) corresponds to the local server time. Here is an example:
You upload a file to the FTP server. Suppose your time zone is GMT+5 and the server is located in the GMT+8 time zone. After you upload the file, it will become 3 hours «younger». If your server supports time zones, it does not happen. The server makes all necessary corrections automatically.
- When you upload a file to the FTP server, the time when the file was last modified is not saved. The time when the file was created will correspond to the time when you finished uploading it to the server. So, the file you have just uploaded to the server becomes a bit «younger» than the initial file.

These differences present certain inconveniences while synchronizing folders with an FTP server, but still this operation will free you from creating a rather complicated synchronization task.

**Local Folder.**

The local folder for synchronization. You can specify the path to the folder manually or you can use the folder selection button to the right from the input field. Also, you can use variables in the path to the folder.

Remote Folder.

The folder on the FTP server for synchronization. You can use variables in the path to the folder.

Include Mask.

The list of file masks that you need to synchronize. You should separate file masks with a comma. All files are specified by default ("*.*").

Exclude Mask

The list of comma-separated file masks that should be excluded from synchronization. For example, you can specify *.* in the Include mask option and *.txt in the Exclude mask option. It will mean that all files except *.txt should be synchronized.

Synchronization mode.

There are 3 options to choose from:

Local => Remote – newer files from the local folder will be copied to the FTP server

Local <= Remote – the reverse operation, i.e. copying new files from the server to the local folder.

Local <=> Remote – bidirectional synchronization. Downloading newer files from the FTP

server and uploading new files to the server.

Include Subfolders.

Select this checkbox if you want to include all subfolders in the specified folders to be included in the synchronization process.

Exact copy.

This option works only when the synchronization is one-directional. It does not make sense in case of bidirectional synchronization and so it is unavailable. If you want to get the exact copy of the initial folder, select this checkbox.

*Note that the "Exact Copy" mode first copies newer files from the source folder to the target folder and then **removes all files from the target folder that are absent in the source folder.***

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7 SSL FTP

Encryption of traffic lets using of the FTP server in a public network safely (SSL - Secure Sockets Layer). At present most types of servers support the SSL FTP. Also there are freeware servers supporting SSL FTP (for example, FileZilla Server). Plugin SSL FTP allows using an ordinary FTP protocol with encryption. Functions of the plugin can be applied for the standard FTP protocol without encryption.

Thus the plugin SSL FTP can replace actions of FTP plugin.

4.7.1 SSL FTP Log On

Performs a connection to the FTP server and authentication of a user.

General

**Host**

Enter the name of the remote host that you want to log into.

Port

Enter the number of the port that you want to use. The default port is 21.

Authentication:**Connect as Anonymous**

Click this check box if the remote server allows anonymous logins.

Username

Enter the name of the log in account.

Password

Enter the password of the log in account.

SSL/TLS Settings

TLS – Transport Layer Security.

TLS mode

Two separate methods were developed to invoke client security for use with FTP clients: Explicit or Implicit. The explicit method is a legacy compatible implementation where FTPS aware clients can invoke security with an FTPS aware server without breaking overall FTP functionality with non-FTPS aware clients. The implicit method requires that all clients of the FTPS server be aware that SSL is to be used on the session, and thus is incompatible with non-FTPS aware clients.

- **None** – plain FTP without encryption. SSL mode is OFF.
- **Implicit** – Negotiation is not allowed with implicit FTPS configurations. A client is immediately expected to challenge the FTPS server with a TLS/SSL ClientHello message. If such a message is not received by the FTPS server, the server should drop the connection.
- **Explicit** – In explicit mode (also known as FTPES), an FTPS client must "explicitly request" security from an FTPS server and then step-up to a mutually agreed encryption method. If a client does not request security, the FTPS server can either allow the client to continue insecure or refuse/limit the connection.
- **Auto** – it is auto-detection of a mode. Please note, that not all types of servers allow auto-detection of a mode.

TLS Flags

Specifies modes of using SSL versions. It is usually enough only to turn on the flag Use TLS.

- Use SSL2
- Use SSL3
- Use TLS

Proxy Settings

SSL FTP Log On

General SSL/TLS settings Proxy settings

Use proxy

Proxy Type:
USER user@FWuser@hostname / PASS pass@FWpass

Proxy Host:
[Empty text box]

Proxy Port:
[Empty text box]

Proxy User:
[Empty text box]

Proxy Password:
[Empty text box]

{V} OK Cancel

Use proxy

If it is necessary to use PROXY, turn on this flag and full in the parameters below. The parameters PROXY can be learned from the documentation for your PROXY or from your network administrator.

Proxy Type

It is necessary to choose the type of PROXY.

- Send command USER user@hostname - Sends the command USER user@hostname to the firewall/proxy. This method is used by many programs like Wingate. The fields 'user name' and 'password' must be left empty.
- Send command SITE (with logon) - First send the user name and password to the proxy (if given), then the command 'SITE machine name'. The fields 'user name' and 'password' are usually needed for this type of proxy.
- Send command OPEN - First send the user name and password to the proxy (if given), then the command 'OPEN machine name'. The fields 'user name' and 'password' are sometimes not needed for this type of proxy.
- USER user@firewalluser@hostname / PASS pass@firewallpass - Use these two commands to logon.
- Transparent - First use the USER and PASS command with the firewall username and password, and then with the target host username and password.
- USER user@hostname firewalluser PASS pass ACCT firewallpass - Use these three commands to logon.

Proxy Host

An IP address or a computer name in the network.

Proxy Port

The number of a port.

Proxy User

A username for the authorization in PROXY.

ProxyPassword

The password for the authorization in PROXY.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.2 SSL FTP Log Off

Allows you to log off an Ftp site, or remote server. No specific settings are associated with this action. For example, when you work from home, you can create a task that Ftps daily files that you have worked on to a remote server in your company's network to protect your data.

4.7.3 SSL FTP Download

Copies remote files to the local computer using the current file transfer type. For example, if you are participating in a software beta program, you can download daily updates automatically to stay up-to-date.

**Tip**

- Click the {V} button to insert a variable that holds the name of the local file or the remote folder.

Remote File

Enter the name of the remote file that you want to copy to the local computer.

Local Folder

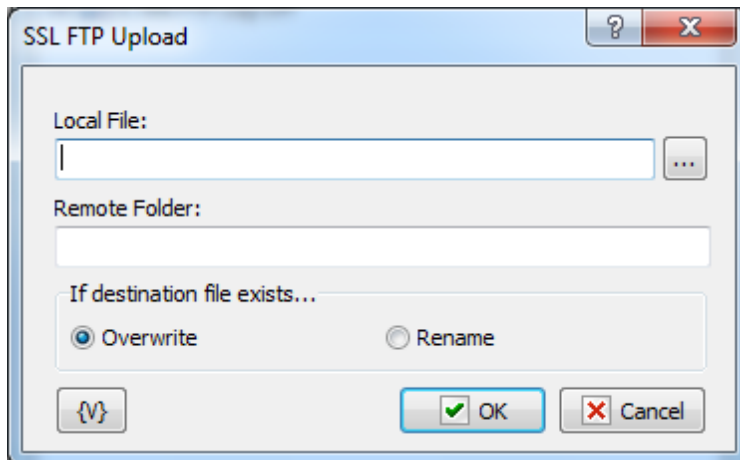

Enter the path and name of the local directory to which you want to copy the remote file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.4 SSL FTP Upload

Allows you to place files on an Ftp site. For example, if you must post daily updated financial reports to a web site, you can create a task to automatically upload the updated reports to the company web site at the end of each day.

**Tip**

- Click the {V} button to insert a variable that holds the name of the local file or the remote folder.

Local File

Enter the name of the local file that you want to copy to the remote server.

Remote Folder

Enter the path and name of the directory on the remote server.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.5 SSL FTP Rename File

Allows you to change the name of files on a remote server. For example, in an FTP session, you can use this action to rename files that you might accidentally overwrite on the remote server

with updated files.

**Tip**

- Click the **{V}** button to insert a variable that holds the new file name or the old file name.

Old File Name

Enter the name of the file that you want to rename.

New File Name

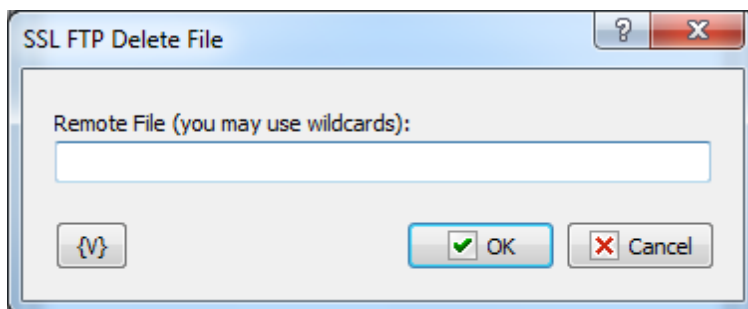

Enter the name that you want to give the file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the **{V}** button.

4.7.6 SSL FTP Delete File

Allows you to remove files from a remote server. For example, you can use this action to remove old backup files on the remote server that are no longer needed.

**Remote File**

Enter the path and file name that you want to delete on the remote server. Click the **{V}** button to insert a variable that holds the path and name of the file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must

place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.7 SSL FTP Change folder

Allows you to switch the current folder on a remote server. For example, during an FTP task that backs up your files, you can use this action to copy files to different directories on the remote server.

Remote Folder

Enter the path or folder name on the remote server that you want to switch to. Click the {V} button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.8 SSL FTP Create Folder

Allows you to create a new folder on a remote server. For example, during an FTP task, you can use this action to create a new folder based on the current date for each set of daily backup files.

Remote Folder

Enter the path or folder name on the remote server that you want to create. Click the {V} button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.9 SSL FTP Remove Folder

Allows you to delete a folder on a remote server. For example, you can create a task to remove company reports that are more than six months old from the remote server.

**Remote Folder**

Enter the path or folder name on the remote server that you want to remove. Click the {V} button to insert a variable that holds the name of the folder.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.10 SSL FTP PWD

Allows you to print the current directory on the remote computer. This action saves the task log to the current directory on the FTP server. Also, you can assign the current directory to a custom variable for future use.

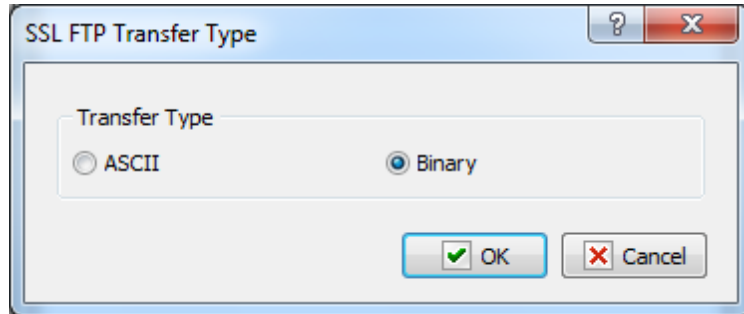

**Assign Remote Folder to Variable**

If you want to assign the name of the current FTP directory to a custom variable, select this

checkbox and type the name of the variable in the field below.

4.7.11 SSL FTP Transfer Type

Sets or displays the type of file you are transferring. For example, if you are transferring Microsoft Word reports to the company server every day, you must set the transfer type to binary. The default transfer type is **binary**.

Transfer Type

Select whether you want to transfer the files as ASCII or binary during an FTP session. You should select **ASCII** when you want to transfer files that contain text strings, such as .html, .txt, or .xml. You should use **Binary** when transferring executable files, such as Office documents, .Exe files, and so forth. In binary mode, files are transferred in one-byte units.

4.7.12 SSL FTP File Loop

Executes a series of commands on files or folders on a remote server during an FTP session.

General tab

**Loop Kind**

Select the items you want to perform actions on: folders only, or files only.

Remote Folder

Enter the path or folder name on the remote server.

Save Results

Enter information about how you want to save the result of the file loop.

Assign File Name to Variable

Enter the name of the variable into which it is necessary to save the file name.

Assign File Size to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the size of the file. This allows to use the file size data in other actions or tasks.

Assign Last Update Time to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the date and the time of the file. This allows to use the last update time information in other tasks or actions.

Date Filter tab

All Files

Click this option to include all files in the file loop.

Find Files Created or Modified

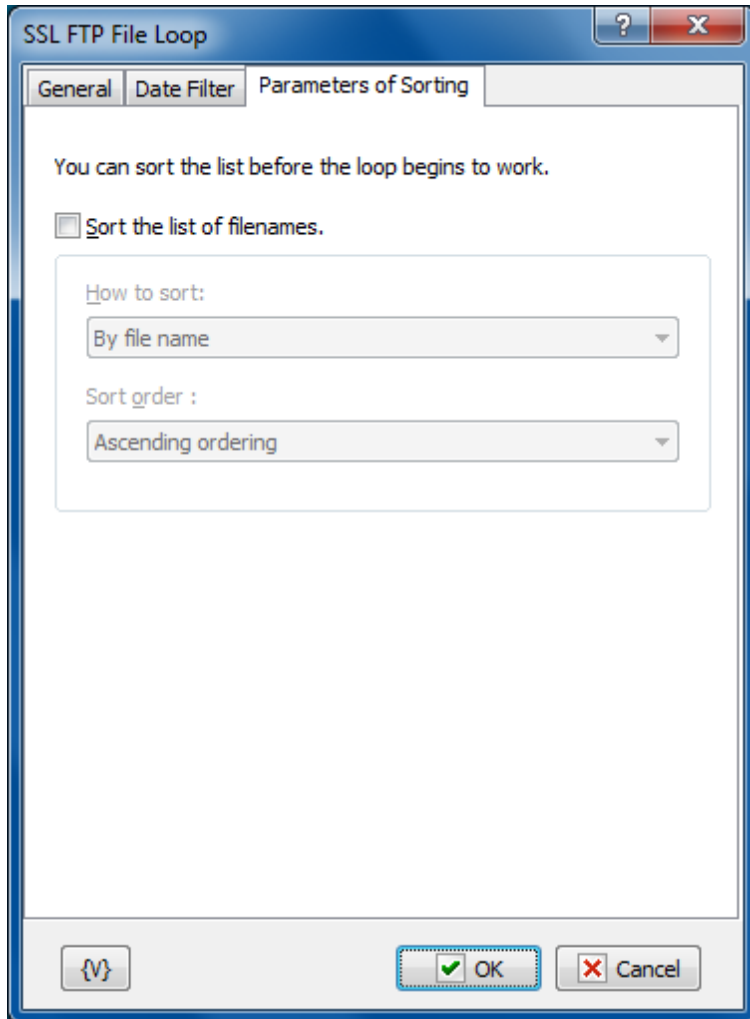

Enter dates and times to include files for certain time periods in the loop.

- **Between** – You can specify two dates explicitly selecting them from a calendar. Or you can specify the expression using variables. This expression should contain the date in the format set on your computer.
- **Newer Than ___ Months**
- **Newer Than ___ Days**
- **Newer Than ___ Minutes**
- **Older Than ___ Months**

- Older Than ____ Days
- Older Than ____ Minutes

Sorting parameters

Parameters of internal sorting of the file list

Sort the list of filenames

Turn on the checkbox if you want to sort the list

How to sort

There are four sorting modes:

- By file name
- By file time
- By file size
- By depth of nested folders

Sort order

There are two modes: ascending or descending ordering

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.7.13 SSL FTP Synchronization

Synchronizes files between a local folder and a remote folder on the FTP server. This high-level operation is very similar to "Synchronize folders", but there are several important differences:

- The time when a file is created on the FTP server is determined with the accuracy of one minute. So, if the difference in the versions of a file is several seconds, no file exchange will take place.
- Some FTP servers do not support time zones. In this case, the time when a file was created (last modified) corresponds to the local server time. Here is an example:
You upload a file to the FTP server. Suppose your time zone is GMT+5 and the server is located in the GMT+8 time zone. After you upload the file, it will become 3 hours «younger». If your server supports time zones, it does not happen. The server makes all necessary corrections automatically.
- When you upload a file to the FTP server, the time when the file was last modified is not saved. The time when the file was created will correspond to the time when you finished uploading it to the server. So, the file you have just uploaded to the server becomes a bit «younger» than the initial file.

These differences present certain inconveniences while synchronizing folders with an FTP server, but still this operation will free you from creating a rather complicated synchronization task.

Local Folder.

The local folder for synchronization. You can specify the path to the folder manually or you can use the folder selection button to the right from the input field. Also, you can use variables in the path to the folder.

Remote Folder.

The folder on the FTP server for synchronization. You can use variables in the path to the folder.

Include Mask.

The list of file masks that you need to synchronize. You should separate file masks with a comma. All files are specified by default ("*.*").

Exclude Mask

The list of comma-separated file masks that should be excluded from synchronization. For example, you can specify *.* in the Include mask option and *.txt in the Exclude mask option. It will mean that all files except *.txt should be synchronized.

Synchronization mode.

There are 3 options to choose from:

Local => Remote – newer files from the local folder will be copied to the FTP server

Local <= Remote – the reverse operation, i.e. copying new files from the server to the local folder.

Local <=> Remote – bidirectional synchronization. Downloading newer files from the FTP

server and uploading new files to the server.

Include Subfolders.

Select this checkbox if you want to include all subfolders in the specified folders to be included in the synchronization process.

Exact copy.

This option works only when the synchronization is one-directional. It does not make sense in case of bidirectional synchronization and so it is unavailable. If you want to get the exact copy of the initial folder, select this checkbox.

*Note that the "Exact Copy" mode first copies newer files from the source folder to the target folder and then **removes all files from the target folder that are absent in the source folder.***

Output Activity to Log

If you want to write the log of synchronization into the task log, switch on this checkbox. The action will put the information about downloaded, uploaded and removed files into the task log.

Output Activity to variable

If you want to write the log of synchronization into a variable, switch on this checkbox and put the variable name in the field. The action will put the information about downloaded, uploaded and removed files into the variable as text.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8 SFTP (SSH FTP)

Plugin unites functions SFTP (according to the protocol SSH). SSH is a very popular protocol on Linux servers. In spite of similarity with FTP protocol, SFTP is an absolutely different protocol of file exchange and has only similarity in appearance with FTP.

The work of the plugin is supported by the console utility PSFTP.EXE from the PUTTY package (free open source software).

4.8.1 SFTP Log On

Connecting to the SFTP server. This action have to be done to provide normal work of the rest of SFTP actions.

The screenshot shows the 'SFTP Open' dialog box with the 'Profile settings' tab selected. The 'General' tab is also visible. The 'Host' field contains 'ftp.company.com' and the 'Port' field contains '22'. The 'Authentication' section has a 'Username' field, a 'Password' dropdown menu set to 'Explicit password', and an empty password input field below it. At the bottom, there are buttons for '{V}', 'OK', and 'Cancel'.

Host

The name or IP-address of the SFTP server. The usage of variables is allowed.

Port

The number of a server port. It is 22 by default. The usage of variables is allowed.

User Name

The name of a user. The usage of variables is allowed.

Password

The password of a user. The usage of variables is allowed.

The screenshot shows the 'SFTP Open' dialog box with the 'General' tab selected. The 'Profile settings' tab is also visible. The text 'Choose connection profile:' is displayed above a list box containing the item 'Default'. At the bottom, there are buttons for '{V}', 'OK', and 'Cancel'.

Choose connection profile

Additional settings of a connection (for example, the usage of a proxy) can be done in a connection profile PUTTY. It is necessary to install PUTTY packet, to do necessary settings and then to save them into the separate profile. This profile can be used when connecting to the server.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.2 SFTP Log Off

This action completes an SFTP session and closes the connection with a server. The action does not required any additional settings.

4.8.3 SFTP Download

This action allows to download a file from a server to a local disc.

Remote File or Folder

Specify the name of the file or the folder which is necessary to download to a local disc. If the folder is specified, the action downloads all files of the remote folder.

Local folder

Specify the folder on a local disc or in a local network where is necessary to download a file or a folder from a server.

Recursively fetch a directory (if a source is a directory)

Switch on this parameter if you want to download the whole folder with all subdirectories. This parameter makes sense only if a folder is specified as a source. If a source is a file, the parameter is ignored.

This mode is similar to [SFTP Synchronization](#)^[170] action.

If a destination file exists (if a source is a file)

This parameter makes sense only if a file is specified as a source. There are 2 alternatives:

- **Rename** – if such file exists, it will be renamed when downloading. In this case, the existent file will be saved.
- **Overwrite** – a file will be downloaded with an original name. If such file exists, it will be overwritten.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.4 SFTP Upload

The action allows to upload files and folders from a local disc to the SFTP server.

**Local File or Folder**

Specify the name of a file or folder which is necessary to upload from a local disc to a server. If a folder is specified, the action uploads all files from the local folder.

Remote Folder

Specify a folder on SFTP server where it is necessary to upload the file or the folder from a local disc.

Recursively fetch a directory (if a source is a directory)

Switch on this parameter if you want to upload the whole folder with all subdirectories. This parameter makes sense only if a folder is specified as a source. If a source is a file, the parameter is ignored.

This mode is similar to [SFTP Synchronization](#)^[170] action.

If a destination file exists (if a source is a file)

This parameter makes sense only if a file is specified as a source. There are 2 alternatives:

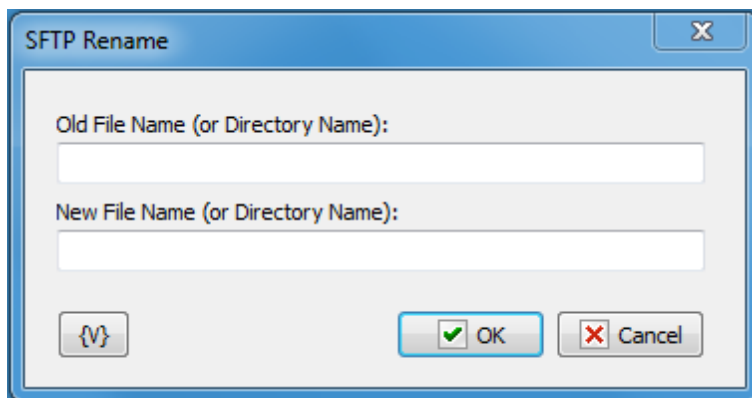

- **Rename** – if such file exists, it will be renamed when downloading. In this case, the existent file will be saved.
- **Overwrite** – a file will be downloaded with an original name. If such file exists, it will be overwritten.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.5 SFTP Rename File of Folder

The action allows to rename a file or a folder on the SFTP server.

Old File Name (or Directory Name)

Specify the name of the file or the folder which are necessary to rename.

New File Name (or Directory Name)

Specify a new name of the file or the folder.

Usage:

It is possible to rename separate files/folders:

```
OldFile.txt -> NewFile.txt  
OldFile.txt -> SubFolder/NewFile.txt
```

It is possible to move one or several files to another folder. For this it is necessary to specify the file names separated by a space and, in the capacity of a new file name, the name of the folder which the files have to be moved into.

```
File1.txt File2.txt -> /home/user/newfolder
```

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.6 SFTP Delete File

The action deletes specified files from the SFTP server.

Remote file

Specify the name of the file that has to be deleted. The usage of a mask is allowed. It is also possible to specify several files separated by a space.

For example:

```
file.dat  
file1.txt file2.txt  
*.txt
```

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.7 SFTP Change Folder

The action changes the current work folder on the server.

Remote folder

Specify a new work folder. It is possible to specify the folder from the root or current folder. For example:

```
/home/user/test
```

```
test/subfolder
```

It is possible to get the current folder during (as a result of) the action [SFTP PWD](#)^[165].

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.8 SFTP Create Folder

The action creates a new folder.

Remote Folder

Specify new folder name.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then

click the {V} button.

4.8.9 SFTP Remove Folder

Allows you to delete a folder on a remote server.

Remote Folder

Enter the path or folder name on the remote server that you want to remove.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.10 SFTP PWD (print working directory)

Allows you to print the current directory on the remote computer.

This action saves the task log to the current directory on the SFTP server. Also, you can assign the current directory to a custom variable for future use.

Assign Remote Folder to Variable

If you want to assign the name of the current FTP directory to a custom variable, select this checkbox and type the name of the variable in the field below.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.11 SFTP File Loop

Allows a task to iterate through the list of files or folders on SFTP server.

General tab

Loop Kind

Select the items you want to perform actions on: folders only, or files only.

Remote Folder

Enter the path or folder name on the remote server.

Include Subfolders

Switch on this checkbox if you want to perform the cycle through all the files, including all nested folders.

Save Results

Enter information about how you want to save the result of the file loop.

Assign File Name to Variable

Enter the name of the variable into which it is necessary to save the file name.

Assign File Size to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the size of the file. This allows to use the file size data in other actions or tasks.

Assign Last Update Time to Variable

Switch on this checkbox and enter the name of the variable into which it is necessary to save the date and the time of the file. This allows to use the last update time information in other tasks or actions.

Date Filter tab

All Files

Click this option to include all files in the file loop.

Find Files Created or Modified

Enter dates and times to include files for certain time periods in the loop.

- **Between** – You can specify two dates explicitly selecting them from a calendar. Or you can specify the expression using variables. This expression should contain the date in the format set on your computer.
- **Newer Than ___ Months**
- **Newer Than ___ Days**
- **Newer Than ___ Minutes**
- **Older Than ___ Months**
- **Older Than ___ Days**
- **Older Than ___ Minutes**

Sorting parameters

Sorting parameters

Parameters of internal sorting of the file list

Sort the list of filenames

Turn on the checkbox if you want to sort the list

How to sort

There are four sorting modes:

- By file name
- By file time
- By file size
- By depth of nested folders

Sort order

There are two modes: ascending or descending ordering.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.12 SFTP Synchronization

Synchronizes files between a local folder and a remote folder on the SFTP server. This high-level operation is very similar to "Synchronize folders", but there are several important differences:

- The time when a file is created on the FTP server is determined with the accuracy of one minute. So, if the difference in the versions of a file is several seconds, no file exchange will take place.
- When you upload a file to the FTP server, the time when the file was last modified is not saved. The time when the file was created will correspond to the time when you finished uploading it to the server. So, the file you have just uploaded to the server becomes a bit "younger" than the initial file.

These differences present certain inconveniences while synchronizing folders with an SFTP server, but still this operation will free you from creating complicated synchronization task.

Local Folder.

The local folder for synchronization. You can specify the path to the folder manually or you can use the folder selection button to the right from the input field. Also, you can use variables in the path to the folder.

Remote Folder.

The folder on the FTP server for synchronization. You can use variables in the path to the folder.

Include Mask.

The list of file masks that you need to synchronize. You should separate file masks with a comma. All files are specified by default ("*. *").

Exclude Mask.

The list of comma-separated file masks that should be excluded from synchronization. For example, you can specify *.* in the Include mask option and *.txt in the Exclude mask option. It will mean that all files except *.txt should be synchronized.

Synchronization mode.

There are 3 options to choose from:

- Local => Remote – newer files from the local folder will be copied to the FTP server
- Local <= Remote – the reverse operation, i.e. copying new files from the server to the local folder.
- Local <=> Remote – bidirectional synchronization. Downloading newer files from the FTP server and uploading new files to the server.

Include Subfolders.

Select this checkbox if you want to include all subfolders in the specified folders to be included in the synchronization process.

Exact copy.

This option works only when the synchronization is one-directional. It does not make sense in case of bidirectional synchronization and so it is unavailable. If you want to get the exact copy of the initial folder, select this checkbox.

Note that the "Exact Copy" mode first copies newer files from the source folder to the target folder and then removes all files from the target folder that are absent in the source folder.

Output Activity to Log

If to switch on this parameter, the action will display the information about operations with files (download, upload, delete files) during the work.

Output Activity to variable

If you want to write the log of synchronization into a variable, switch on this checkbox and put the variable name in the field. The action will put the information about downloaded,

uploaded and removed files into the variable as text.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.13 SFTP File Permissions

The action allows you to modify the file permissions on files and directories on the server.

The file permissions on the SFTP server are assigned like in the UNIX systems. Every file or folder has 3 groups of permissions:

- **Owner permissions;**
- **Group permissions.** That is, the permissions of users of the group, which the file owner belong to.
- **Public permissions.** That is, the permissions for all the rest users.

Every group contains 3 types of permissions:

- **Read** - permission to read the file
- **Write** - permission to write to the file
- **Execute** - permission to execute the file

Please, notice that Checkboxes have three positions:

- **Switched on** – this means that you want to set a permission
- **Switched off** – this means that you want to remove a permission
- **Grayed, or intermediate state** – this means that you want to leave this permission without changing.

By default, all the checkboxes are in Grayed state.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.8.14 SFTP Command

The action allows to perform a arbitrary SFTP command and save the result of performing into a variable.

**SFTP command**

Specify any SFTP command. For example, the command *help*.

Save Response to Variable

Specify the name of the variable, into which it is necessary to save the result of command performing as a text.

Variable name can be empty. In this case the text of the result will be ignored.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.9 Dial-Up

The actions Dial-Up can be used for such Internet connections as these:

- Connection by the use of an usual telephone modem;
- VPN of connections;
- Connections to Internet through mobile net by means of a mobile modem.

These connections use the same system interface.

4.9.1 Dial Up/Hang Up

Establishes or disconnects a Windows RAS connection, also known as Dial Up Networking. Usually this feature is used to make a connection to the Internet and then complete a task and disconnect from the Internet. For example, you can create a task to automatically connect to the Internet every morning and check e-mail.

Dial-up Connection

Select the name of the dial-up connection that you want to connect or disconnect. You create this connection in the Windows **Control Panel**.

How to Use the Dial-up Connection

Select one of the following options to specify the action on the connection:

- **Disconnect this Connection** - breaks the connection to the Internet or remote network.
- **Establish this Connection** - connects the computer to the Internet or remote network.

Connection Parameters

Enter the following optional parameters to establish a connection:

- **Domain**
- **Username**
- **Password**
- **Callback Number**
- **Number of Attempts**

4.9.2 Check connection

Checks the status of the selected dial-up connection and assigns the corresponding value to a user variable: TRUE if the connection is active and FALSE otherwise. This value can be later used in the "IF Then" action as a Boolean one.

Dial-Up connection

Select the connection you need from the list.

Assign Connection Status to Variable

Specify the name of the variable the status of the connection should be assigned to.

4.10 Variables

4.10.1 Create Variable

Creates a new variable when you run a task. If you create a variable and then use it in several different tasks, you can change the variable once and update every task at the same time. The action allows to create both a global variable and a local one within a task. Local variables can also be generated by means of creating a list of local variables (see [Local variables tab](#)^[47] of task editor).

Variable Name

Enter the name of the variable you want to set the value of.

Variable Kind

- **Global variable (for all tasks)** – in this case a global variable will be created. If the variable already exists, a specified value will be assigned to it.
- **Local variable (for this task only)** – in this case a local variable will be created within a task. The local variable will be deleted from the memory automatically when the task is finished. See the chapter [Local Variables](#)^[11] for details about local variables.

Variable Value

Enter the value that you want to set for the variable.

Expand variable value.

If this parameter is on, RoboTask computes the value of an expression (that is, expands variables in the expression) before assigning a value to the specified variable.

Otherwise, the value is assigned without expanding variables. In this case the value is computed while further using the variable. Meanwhile, the variable value and the value of all variables are expanded recursively until the very end.

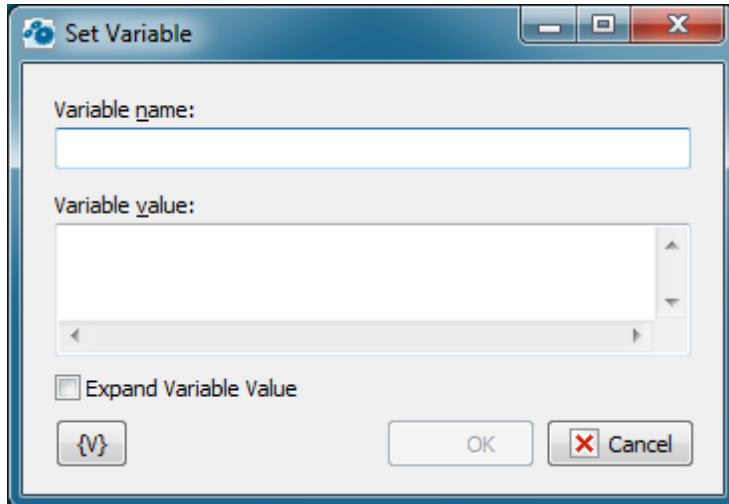

There can be necessity of using both modes in tasks:

- **Expand variable value is on** – when you have to fix the value in the moment of assigning it to the variable. For example: current time
- **Expand variable value is off** – when you have to compose a complex expression of many variables and then you have to use only one variable in further steps. You also don't need to turn on the expanding of variables if an assigned expression contains a static text and doesn't contain other variables.

By default, the parameter is off.

4.10.2 Set Variable

Defines the value of a variable when you run a task.

Variable Name

Enter the name of the variable you want to set the value of.

Variable Value

Enter the value that you want to set for the variable.

Expand variable value.

If this parameter is on, RoboTask computes the value of an expression (that is, expands variables in the expression) before assigning a value to the specified variable.

Otherwise, the value is assigned without expanding variables. In this case the value is computed while further using the variable. Meanwhile, the variable value and the value of all variables are expanded recursively until the very end.

There can be necessity of using both modes in tasks:

- **Expand variable value is on** – when you have to fix the value in the moment of assigning it to the variable. For example: current time
- **Expand variable value is off** – when you have to compose a complex expression of many variables and then you have to use only one variable in further steps. You also don't need to turn on the expanding of variables if an assigned expression contains a static text and doesn't contain other variables.

By default, the parameter is off.

4.10.3 Remove Variable

Deletes a variable when you run a task. This ensures that all variables are cleared from memory if a new task starts.

**Variable Name**

Enter the name of the variable you want to delete.

4.10.4 Increment Variable

Increments or decrements a variable by a specified value.

**Variable Name**

Specify a variable name you want to increment or decrement

Increment by

Enter a positive or negative value

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.10.5 Delimit variable

Turns a string with any delimiters into a standard comma-separated string. This standard comma-separated string can be used in user variables [as an array](#)^[10].

String to process

Specify the string to process. You can use variables.

Delimiters

Select which delimiters should be processed. You can select one or several delimiters.

Quote Char

Specify the character that should be interpreted as quotation marks.

Assign standard comma-separated text to variable

Specify the variable the processed string should be assigned to.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.11 Task Commands

4.11.1 Enable Task

Enables a task. Disabled tasks cannot run automatically, i.e. their triggering events are disabled.

**Specified Task**

Press Select button and choose the task from the list.

This task

If you want to enable this task without selection choose this option.

4.11.2 Disable Task

Disables a task. Disabled tasks cannot run automatically, i.e. their triggering events are disabled.

**Specified Task**

Press Select button and choose the task from the list.

This task

If you want to disable this task without selection choose this option.

4.11.3 Start Task

Runs a task. This action is useful if you want to run several tasks in a series. For example, you can create several different tasks in a series based on certain conditions that are detected in the following order:

1. A task that connects to the Internet and checks the e-mail server,
2. A task that logs off if no e-mail is present,
3. A task that displays a message box if you have received e-mail.

Task

Select a existing task.

Wait for Finish

Click this check box to ensure that the **Start Task** action starts a task and waits for completion of that task, then continues running. If the check box is clear, the action starts a task and continues running immediately.

Parameters

You can pass some parameters into started task. By default, the list of parameters is empty. You need write down parameters like the text, each line should be like:

ParameterName=ParameterValue

- **ParameterName** – the name of parameter, any word consisting of letters and numbers;
- **ParameterValue** – value of parameter like any set of symbols.

You can refer to these parameters in the task as the local variables of the task. You don't need declare them in the task. Appropriate variables will appear automatically when the task is started.

Pass of parameters of a task is used when you handle errors. In this case the fixed set of parameters is passing into the task:

- **LastErrorTaskID** – the internal ID of the task, in which an error was raised. It is a formal identifier of a task like a number.
- **LastErrorTaskName** - the name of the task, in which an error was raised.

- **LastErrorTaskExternalName** –the External Name of the task, in which an error was raised.
- **LastErrorStep** – the number of the step (starting from 1), in which an error was raised.
- **LastErrorCode** – code of the error. There is the particular set of error codes for any type of actions (see description of actions). By default – 0.
- **LastErrorDescription** – the description of the error. It depends on a type of action. By default, it is the line "General error".

Required start

This parameter guarantees the start of a task. The problem is that the task can be working when you try to start it. In the most cases that doesn't matter because you need only to start the task at the appointed moment. In this case the action just sent the signal to start the task. If the task is idling, it will be started. If the task is already started, the RoboTask ignores the signal of a start because the task works by now.

But a task can be started with parameters and fulfill different actions against parameter values. Switch on this parameter if you need to ensure start up of a task when each effort to start a task. In this case the action will do efforts to start the task until a successful result.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.11.4 Stop Task

Allows you to stop the selected task.

Specified Task

Press Select button and choose the task from the list.

This task

If you want to stop this task without selection choose this option.

4.11.5 Wait for Task

Waits until the selected task is finished. This action pauses the current task until the selected task is finished. If the selected task is not running at the moment when the action is due, the current task is not paused.

If the selected task is not finished during the specified timeout, the "Timeout is over" error is generated.

**Task**

Select a task from the list.

Waiting

Specify the timeout in seconds to wait for the task to be finished. You can also specify an infinite timeout.

4.11.6 Task status

This action reads the status of a specified task and writes it into a variable. The value can be a number from 0 to 4 or as a string:

- **Manual** – (0). A task without triggers or with switched off triggers in the idle mode. It is possible to run the task manually or from another task.
- **Idle** – (1). A task is in the idle mode and has active triggers. It is possible both running manual and automatically when a trigger starts.
- **Disabled** – (2). A task is in the edit mode. The running of the task does not possible.
- **Running** – (3). A task is performed. The repeat running is possible only after the completion of the task.
- **Stopping** – (4). A task has got the signal to stop and is waiting for the end of the active step. The task will be stopped only after the end of the active step.

Task to Check

Specify the task for the reading its status. You can select the task of a list pressing the button to the right of the edit field.

Save Status to Variable

Specify the name of the variable in which the status must be saved.

Save status as

Integer value – is a status as an integer number from 0 to 4.

String value – is a status as a string: *Manual, Idle, Disabled, Running, Stopping*

4.12 Loops and Flows

4.12.1 File Loop

Allows a task to iterate through the results of a file search. For example, you can create a task that searches all the employee status reports and identifies all status report files for the first of the month.

General tab

Search for Files

Enter the files that you want to include in the loop. You can click the browse buttons to the right of the list to add files, add folders, and remove items from the list.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- **C:\Text Files*.txt** - all the files with the .txt extension in the C:\Text Files folder.
- **C:\Doc Files\mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- **{bakext}** - file mask(s) from the {bakext} variable.

Exclude Masks (Comma Separated)

Enter one or more file masks separated by commas for files that you do not want to include in the loop.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- ***.txt** - all the files with the .txt extension.
- **mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- ***.tmp, *.\$\$\$, *.bak** - all the files with the .tmp, .\$\$\$ and .bak extensions.
- **{bakext}** - file mask(s) from the {bakext} variable.

Recurse to Subfolders

Click this check box to include subfolders in the loop.

Assign Current Filename to Variable

The current filename and path to the file in the loop is stored in the variable that you specify. You can use this information in other actions.

Without Full Path

Click this check box to save only the filename and not the path to the variable.

Assign File Size to Variable

The current file size in the loop is assigned to the variable that you specify. You can use this information in other actions.

Assign File Time to Variable

The current time of the file in the loop is assigned to the variable that you specify. You can use this information in other actions.

Date Filter tab

All Files

Click this option to include all files in the file loop.

Find Files Created or Modified

Enter dates and times to include files for certain time periods in the loop.

- **Between**
- **Newer Than ___ Months**
- **Newer Than ___ Days**
- **Older Than ___ Months**
- **Older Than ___ Days**

Sorting parameters

Parameters of internal sorting of the file list

Sort the list of filenames

Turn on the checkbox if you want to sort the list

How to sort

There are four sorting modes:

- By file name
- By file time
- By file size
- By depth of nested folders

Sort order

There are two modes: ascending or descending ordering

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.2 Text Loop

Allows a task to iterate through all lines of the text that you specify. You can enter text in the parameters of the action or you can refer to a text file.

External Text File

Enter the path and name of text file or click the browse button to select a text file.

Specified Text

Enter the text you want to loop through.

Store Current Line to Variable

Enter a variable name to store with the current line of text.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must

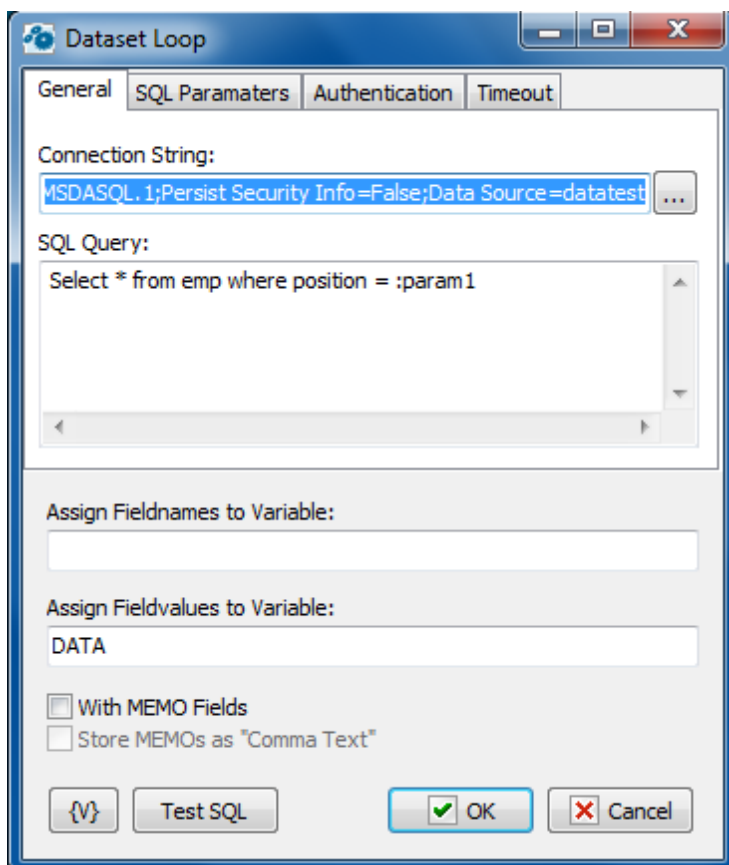

place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.3 Dataset Loop

Allows a task to iterate through the values of the results of an SQL query. For example, you might create a task that connects to the company human resources database and queries for all records of employee sick leave reports every month and saves a report to a file.

Important

- You must be familiar with SQL syntax to use this action.

Connection String

A string with attribute/value pairs for information required to log on to a database and point to a specific database. Click the browse button to open the Microsoft **Data Link Properties** dialog box. You can press F1 to access Help about this dialog box.

SQL Query

Enter the query string in SQL syntax.

Assign Field Names to Variable

Stores the field names separated by commas in a specified variable.

Assign Field Values to Variable

Stores the field values separated by commas in a specified variable.

With Memo Fields

Specifies that the query should include memo fields.

Store Memos as "Comma Text"

Indicates that the memo fields should be stored as comma delimited text.

Test SQL

Allows you to test the SQL syntax of your query.

SQL parameters

Sometimes using of parameters of a query is more convenient instead of generation of the query by means of variables. For example, when the variable value contains quotes or another special symbols. If you use variables (or macro substitution) when forming SQL inquiry, availability such symbols can "break" the syntax of the query and you will get a runtime error.

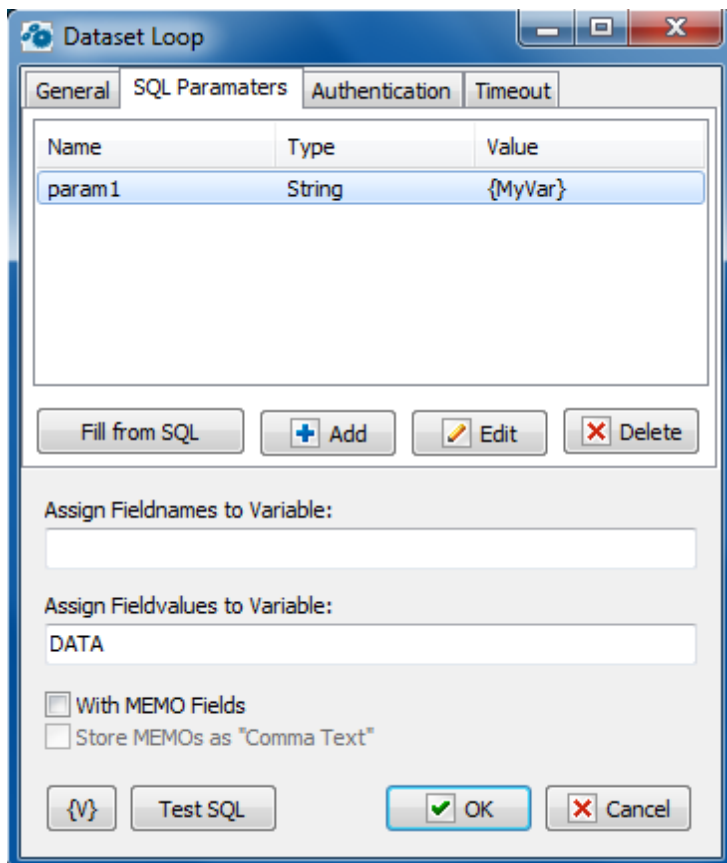

Parameters SQL are designated in the inquiry by means of colon (:) before the parameter name.

For example:

```
Select * from employee where hiredate > :dt and salary >= :amount  
:dt and :amount are parameters of the query.
```

Parameters can be several types:

- **String** – any string
- **Integer** – an integer number
- **Float** – a real number or the number with a floating dot.
- **Boolean** – a logical value True or False.
- **DateTime** – a date and time. The value of such parameter must be defined in current system format of date and time (see the system regional settings). Notice that using of date-time can have its own characteristics for different databases. For example, it is better specify such parameters for the MySQL as a string parameter in the format YYYY-MM-DD or YYYY-MM-DD hh:nn:ss.

Fill from SQL

Fill the list of parameters from the current query. If a parameter is already in the list, this parameter will be without change. The function fills only the missing parameters in the list.

Add

Add a parameter manually. You will be proposed to type or select from the list the parameter name, select the parameter type and input an expression as the parameter value.

Using of variables in a parameter name and in its value is allowed. The RoboTask will substitute variable values instead of variables before performing the SQL.

Edit

Edit the properties of the selected parameter.

Delete

Delete the selected parameter from the list.

If you specify the parameter which is absent in the query, the action ignores this parameter when performing and writes the proper warning in the log of the task.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.4 Window loop

Enumerates windows existing in the system and allows you to assign their parameters to variables. You can use these values inside the loop.

General

Assign Window Caption to variable

You can specify the variable you want to assign the window caption to. If you clear this checkbox, the window caption will not be saved.

Assign Window Class to variable

You can specify the variable you want to assign the window class to. If you clear this checkbox, the window class will not be saved.

Assign Window Handle to variable

Specify the variable you want to assign the window handle to. You cannot disable this option because the handle of a window is its unique identifier. You can use the value of this variable in the "Window Command" action.

Window Filters

Process Hidden Windows

If you want to enumerate hidden windows, you should select this checkbox. By default, Window loop enumerates only visible windows.

Process Child Windows

Select this checkbox to enumerate child windows.

Window caption

You can use this parameter to apply a filter to the captions of windows. Either select the caption you need from the list or type it manually.

Window class

You can use this parameter to apply a filter to the classes of windows. Either select the class you need from the list or type it manually.

The "Window caption" and "Window class" lists depend on the "Process Hidden Windows" and "Process Child Windows" checkboxes.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.5 Simple Loop

Allows a task to iterate through a loop.

**Start From**

Enter the number at which to start the loop.

To

Enter the number at which to end the loop.

Destination Variable

Stores the current value of the loop. For example, if you enter 1 in the **Start From** box and 5 in the **To** box, then, in the first iteration, the destination variable contains 1. In the second iteration, the destination variable contains 2, and so forth.

4.12.6 While loop

The **While loop** is used if the number of iterations is unknown, but you know the condition that should be met for the loop to continue. The settings of this action are similar to the **If.. then** action and it has similar parameters.

Attention: it is possible to make an infinite loop with **While Loop** if you specify the condition incorrectly. So, be careful while creating a task if you do not intend to make an infinite loop, of course.

Compare Values As

Select the type of data for the expressions that you want to compare.

- **As String** - compares two values with alphanumeric characters.
- **As Number** - compares two integer values.
- **As Date and Time** - compares two date/time values.
- **As Boolean** - checks for a true/false or yes/no condition. If you select this option, the **If Value Is** option appears, allowing you to select the condition of the Boolean.

If Value Is

Appears if you select **As Boolean** in the **Compare Values As** area. This option allows you to set the value of the Boolean check. You can select false for certain actions to occur if a condition does not exist. You can select true for certain actions to occur if a condition does exist.

First Operand

Enter the value of the first expression you want to compare.

Comparison Type

Select the operator for the comparison from the following:

- = Equal to
- <> Not equal
- >= More than or equal to
- > More
- <= Less than or equal to
- < Less than

Case Sensitive

Click to make the comparison dependent on whether upper case or lower case characters are used in the expressions.

Second Operand

Enter the value of the second expression you want to compare.

It is possible to use a combination from several conditions in the actions *If..Then*^[198], *ElseIf..Then*^[201] and *While Loop*. To add a condition, press the button *Add Another Condition*. You will see the similar dialog of editing of the comparison condition.

If you use more than one condition, you will see the list of conditions instead of parameters of conditions.

The combination of conditions

Two variants of the combination of conditions are possible.

- **Match all of the following conditions** – the common result of the comparing will be True if all enumerated conditions return the result True (logical AND).
- **Match any of the following conditions** - the common result of the comparing will be True if at least one of the enumerated conditions returns the result True (logical OR).

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.7 End Loop

Indicates the end of the loop block. Any loop, including a file loop, simple loop, and so forth,

must contain the corresponding **End Loop** action.

4.12.8 Break

Stops the execution of the current loop so that the task can continue executing the actions after the **End Loop** action. The **Break** action is often used in conjunction with the **If Then** action.

4.12.9 Continue

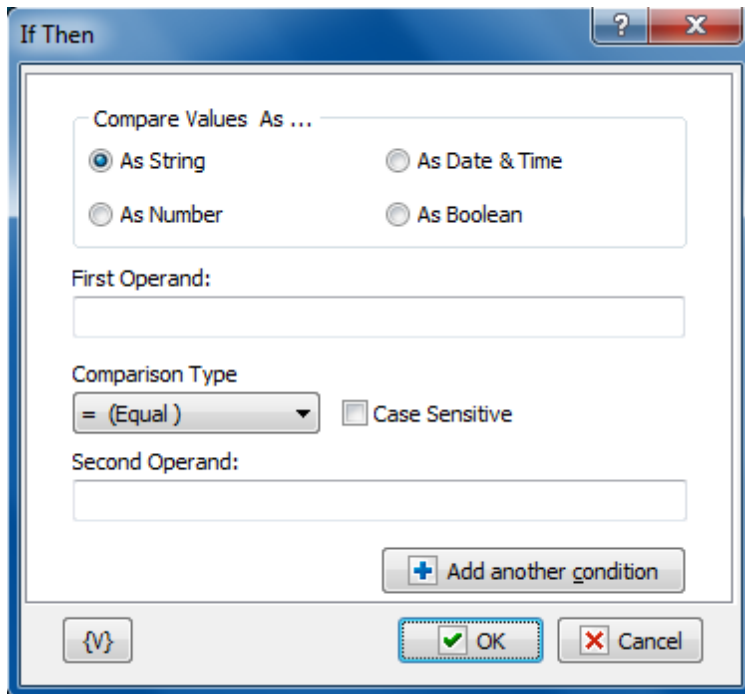

Skips all the actions between it and the **End Loop** action and begins a new iteration. No specific settings are associated with this action. The **Continue** action is used in conjunction with the **If Then** action.

4.12.10 If Then

Allows a task to make a comparison of several conditions and execute actions based on that comparison. You can use this action to run a specific statement or a block of statements, depending on the value of a condition. **If...Then...Else** statements can be nested to as many levels as you need.

Important

- The **If Then** action must be used in conjunction with the **End If** action.

Compare Values As

Select the type of data for the expressions that you want to compare.

- **As String** - compares two values with alphanumeric characters.
- **As Number** - compares two integer values.
- **As Date and Time** - compares two date/time values.
- **As Boolean** - checks for a true/false or yes/no condition. If you select this option, the **If Value Is** option appears, allowing you to select the condition of the Boolean.

If Value Is

Appears if you select **As Boolean** in the **Compare Values As** area. This option allows you to set the value of the Boolean check. You can select false for certain actions to occur if a condition does not exist. You can select true for certain actions to occur if a condition does exist.

First Operand

Enter the value of the first expression you want to compare.

Comparison Type

Select the operator for the comparison from the following:

- = Equal to
- <> Not equal
- >= More than or equal to
- > More
- <= Less than or equal to
- < Less than

Case Sensitive

Click to make the comparison dependent on whether upper case or lower case characters are used in the expressions.

Second Operand

Enter the value of the second expression you want to compare.

It is possible to use a combination from several conditions in the actions *If..Then*, *ElseIf..Then* [201] and *While Loop* [195]. To add a condition, press the button *Add Another Condition*. You will see the similar dialog of editing of the comparison condition.

If you use more than one condition, you will see the list of conditions instead of parameters of conditions.

The combination of conditions

Two variants of the combination of conditions are possible.

- **Match all of the following conditions** – the common result of the comparing will be True if all enumerated conditions return the result True (logical AND).
- **Match any of the following conditions** - the common result of the comparing will be True if at least one of the enumerated conditions returns the result True (logical OR).

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.11 Else

Allows a task to execute an action if certain conditions are not met. This action is used in conjunction with the **If Then** action. You can use this action to run a specific statement or a block of statements, depending on the value of a condition. If...Then...Else statements can be nested to as many levels as you need. No specific settings are associated with this action.

4.12.12 End If

Indicates the end of the **If Then** block.

4.12.13 Elseif Then

This action allows to build a construction of a complex selection with several conditions. For example:

```
If <condition1> then
  DoSomething1
ElseIf <condition2> then
  DoSomething2
ElseIf <condition3> then
  DoSomething3
.....
Else
  DoSomethingN
End if
```

This action can be put in the block "If Then - EndIf" (between [If..Then](#)^[198] and [End If](#)^[201]).

Such construction works in the following way:

- RoboTask checks the condition *<Condition1>*. If the condition is fulfilled (the logical value true) then RoboTask performs the steps *DoSomething1*.
- Otherwise, RoboTask checks the next condition *<Condition2>*. If the condition is fulfilled (the logical value True) then RoboTask performs the steps *DoSomething2*
- Otherwise, RoboTask checks the next condition *<Condition3>*. And so on.
- If none of enumerated conditions is fulfilled, the performing of the task moves to the block Else and then RoboTask performs the steps *DoSomethingN*.

Of course, it is possible to realize this algorithm by means of actions If..Then, Else, and End If. But apparently such construction is less convenient and less demonstrable. An algorithm with three conditions will look like this:

```
If <condition1> then
```

```
DoSomething1
Else
  If <condition2> then
    DoSomething2
  Else
    If <condition3> then
      DoSomething3
    Else
      DoSomethingN
    End If
  End If
End If
End if
```

The parameter editing dialog of the action **ElseIf Then** is completely identical to the window of configuration for the action If Then.

Compare Values As

Select the type of data for the expressions that you want to compare.

- **As String** - compares two values with alphanumeric characters.
- **As Number** - compares two integer values.
- **As Date and Time** - compares two date/time values.
- **As Boolean** - checks for a true/false or yes/no condition. If you select this option, the **If Value Is** option appears, allowing you to select the condition of the Boolean.

If Value Is

Appears if you select **As Boolean** in the **Compare Values As** area. This option allows you to set the value of the Boolean check. You can select false for certain actions to occur if a condition does not exist. You can select true for certain actions to occur if a condition does exist.

First Operand

Enter the value of the first expression you want to compare.

Comparison Type

Select the operator for the comparison from the following:

- = Equal to
- <> Not equal
- >= More than or equal to
- > More
- <= Less than or equal to
- < Less than

Case Sensitive

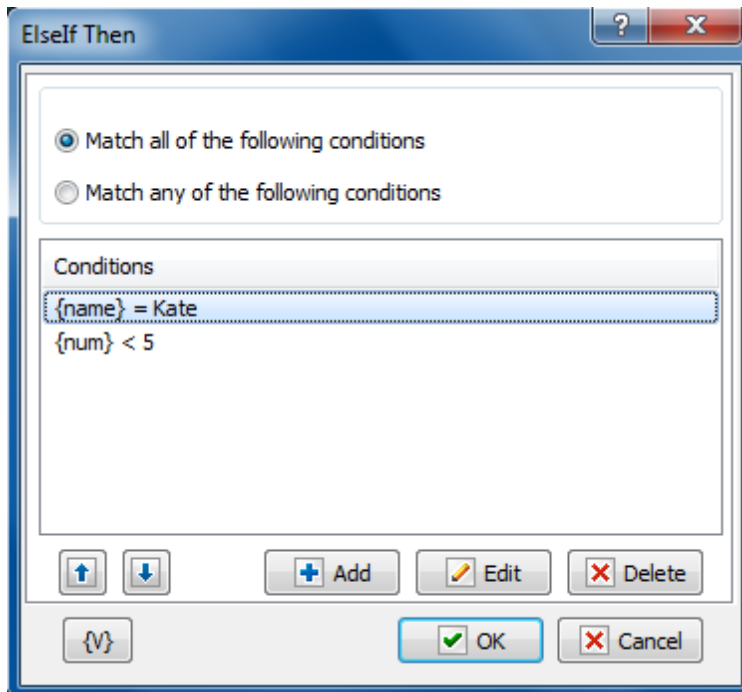

Click to make the comparison dependent on whether upper case or lower case characters are used in the expressions.

Second Operand

Enter the value of the second expression you want to compare.

It is possible to use a combination from several conditions in the actions *If..Then*^[198], *ElseIf..Then* and *While Loop*^[195]. To add a condition, press the button *Add Another Condition*. You will see the similar dialog of editing of the comparison condition.

If you use more than one condition, you will see the list of conditions instead of parameters of conditions.

The combination of conditions

Two variants of the combination of conditions are possible.

- **Match all of the following conditions** – the common result of the comparing will be True if all enumerated conditions return the result True (logical AND).
- **Match any of the following conditions** - the common result of the comparing will be True if at least one of the enumerated conditions returns the result True (logical OR).

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.12.14 Exit

This action makes an immediate exit from the current task. No specific settings are associated with this action.

4.13 Window

4.13.1 Window Command

Manipulates certain windows that you specify.

Window Selection Mode

- **Use Window Parameters.** In this case it is necessary to specify parameters of a required window: Window Caption, Window Class, compliance mode, etc. (see the description below).
- **Use Window Handle.** In this case it is necessary to specify a Window Handle. Handle is a number, an identifier of a window. It can be got, for example, in the action "Window loop". The Window Handle uniquely identifies the window in a system, so the rest of window parameters have no sense.
- **Use Current Window.** In this case a current active window is used. For example, if the necessary window was activated in the previous actions of a task, there is no need to specify window parameters again. Just use the current active window.

Window Caption

Enter or select the caption of the window that you want to manipulate with the action you select in the **Action** list. You can enter part of a window caption.

Caption Must Match Exactly

Select this check box if you want to manipulate only the window that exactly matches the window caption you selected. This check box is cleared by default so that the task can manipulate windows that contain only part of the window caption entered in the **Window Caption** box. For example, you can enter <notepad> for the window with a caption <Untitled - Notepad>.

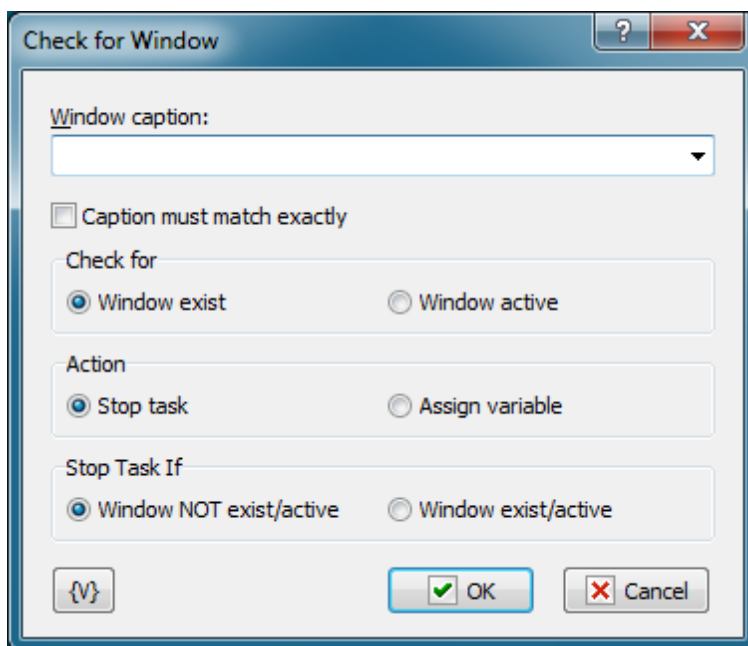

Action

Select the action for manipulating the window.

- **Focus** - makes the window active.
- **Minimize** - reduces the window to an icon on the Windows taskbar.
- **Maximize** - restores the window to fill the entire screen.
- **Restore** - restores the window to its previous state.
- **Close** - closes the window.
- **Hide** - hides the window from view on the screen and Windows taskbar.
- **Unhide** - displays the hidden window.

4.13.2 Check for Window

Checks to see if a window exists or is active. For example, you might want to create a task that starts your HotSync Manager for your Palm PDA every day and synchronizes the Palm device data with Outlook. You might want to check for the existence of the HotSync Manager window to ensure that it has started.

Window Caption

Select the name of the window from the dropdown list. The contents of this list vary with the applications currently launched on your computer.

Caption Must Match Exactly

Click the check box to check only windows that match the entire window caption. If this check box is clear, the action checks for windows that partially match the caption.

Check For

Select one of the following options to check for existing windows or windows that are open.

- **Window Exist**

- **Window Active**

Abort Task If

Stops task executing according with selected option:

- **Window Not Exists/Active** - stops the task if the window does not exist or is not active.
- **Window Exist/Active** - stops the task if the window exists or is active.

4.13.3 Wait for Window

This action is used to synchronize the task with opening or closing a certain window. The action pauses the task and waits for the necessary window operation for the specified timeout and after that resumes the task. If the action does not detect the necessary window operation within the timeout, the "Timeout is over" error occurs.

**General tab**

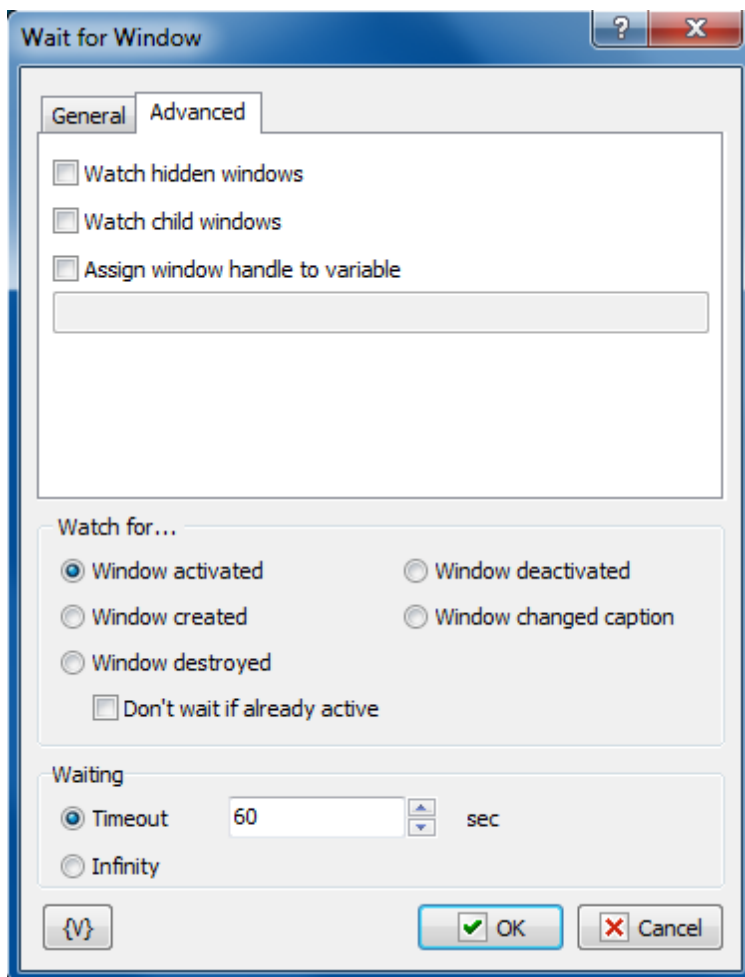

Window Caption – Window caption. You can specify only the distinctive part of the caption if the window has no constant caption. You can select the window you need from the list if you

click the button to the right from the input field.

Caption must match exactly – If you need the window caption to match the specified string exactly, select this checkbox.

Window class – Window class (or window type). You should either type the window class manually or select the window you need from the list by clicking the button to the left from the input field. You can type part of the window class as well.

Class name must match exactly – If you need the window class to match the specified string exactly, select this checkbox. The class of a window does not change all the time the window exists. So, as a rule, you have to enable this option.

Advanced tab

Watch hidden windows – select this checkbox if you want the action to monitor hidden windows.

Watch child windows – select this checkbox if you want the action to monitor child windows. As a rule, these windows are dialog boxes and secondary windows opened by Windows applications.

Assign window handle to variable – if you want to save the HANDLE (or the system number) of a window to a variable, type the name of this variable in the field. Otherwise leave the field empty. The HANDLE of a window is a unique window identifier. And you can use it

later in the Window command action or in Basic script while using it in the script of system API functions.

Common settings

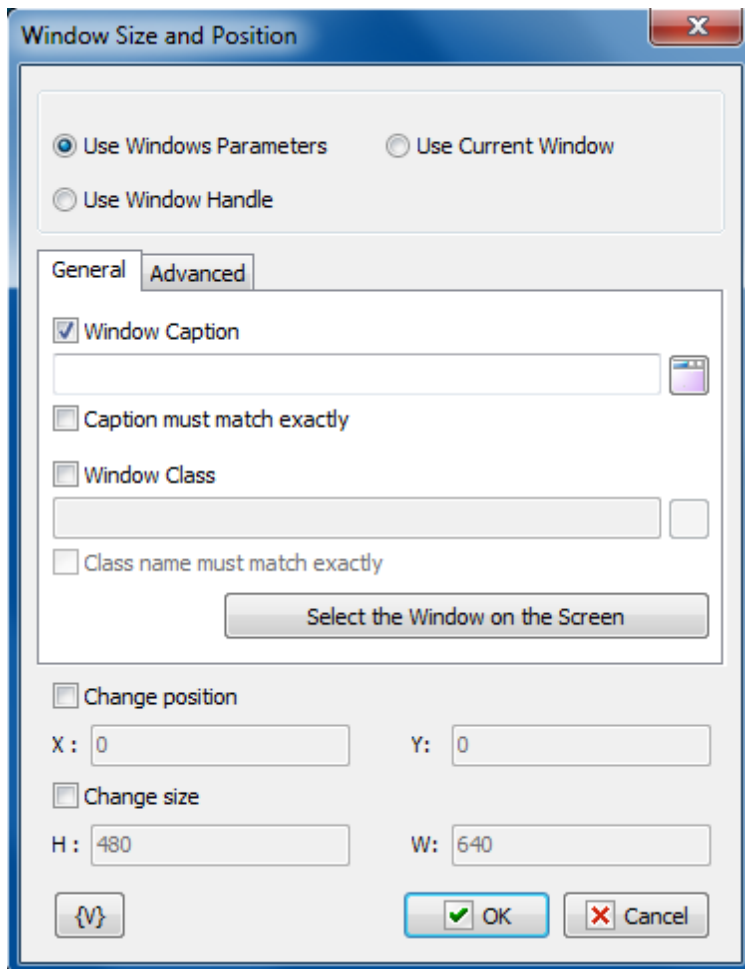

Watch for – select the window operation to wait for. There are 4 options to choose from:

- Window activated;
- Window created;
- Window destroyed;
- Window deactivated;
- Window changed caption.

Waiting – specify the timeout in seconds or select the Infinity option.

4.13.4 Window Size and position

This action allows to change sizes and position of a specified window. The dialog of parameter editing resembles the editor of parameters of the action "[Window command](#)^[204]"

Window Selection Mode

- **Use Window Parameters.** In this case it is necessary to specify parameters of a

required window: Window Caption, Window Class, compliance mode, etc. (see the description below).

- **Use Window Handle.** In this case it is necessary to specify a Window Handle. Handle is a number, an identifier of a window. It can be got, for example, in the action "Window loop". The Window Handle uniquely identifies the window in a system, so the rest of window parameters have no sense.
- **Use Current Window.** In this case a current active window is used. For example, if the necessary window was activated in the previous actions of a task, there is no need to specify window parameters again. Just use the current active window.

Window Caption

Enter or select the caption of the window that you want to manipulate with the action you select in the **Action** list. You can enter part of a window caption.

Caption Must Match Exactly

Select this check box if you want to manipulate only the window that exactly matches the window caption you selected. This check box is cleared by default so that the task can manipulate windows that contain only part of the window caption entered in the **Window Caption** box. For example, you can enter <notepad> for the window with a caption <Untitled - Notepad>.

Change position

Switch on this checkbox if you want to change a window position. After that, fill in parameters X and Y.

X – Specify the horizontal position of the left window edge. The usage of variables is allowed. The result of the expression must be an integer. Otherwise, the action uses default value, which is 0.

Y – Specify the upright position of the upper window edge. The usage of variables is allowed. The result of the expression must be an integer. Otherwise, the action uses default value, which is 0.

Change size

Switch on this checkbox if you want to change a window size. After that, fill in parameters H and W.

H – Specify a new height of the window. The usage of variables is allowed. The result of the expression must be an integer. Otherwise, the action uses default value, which is 480.

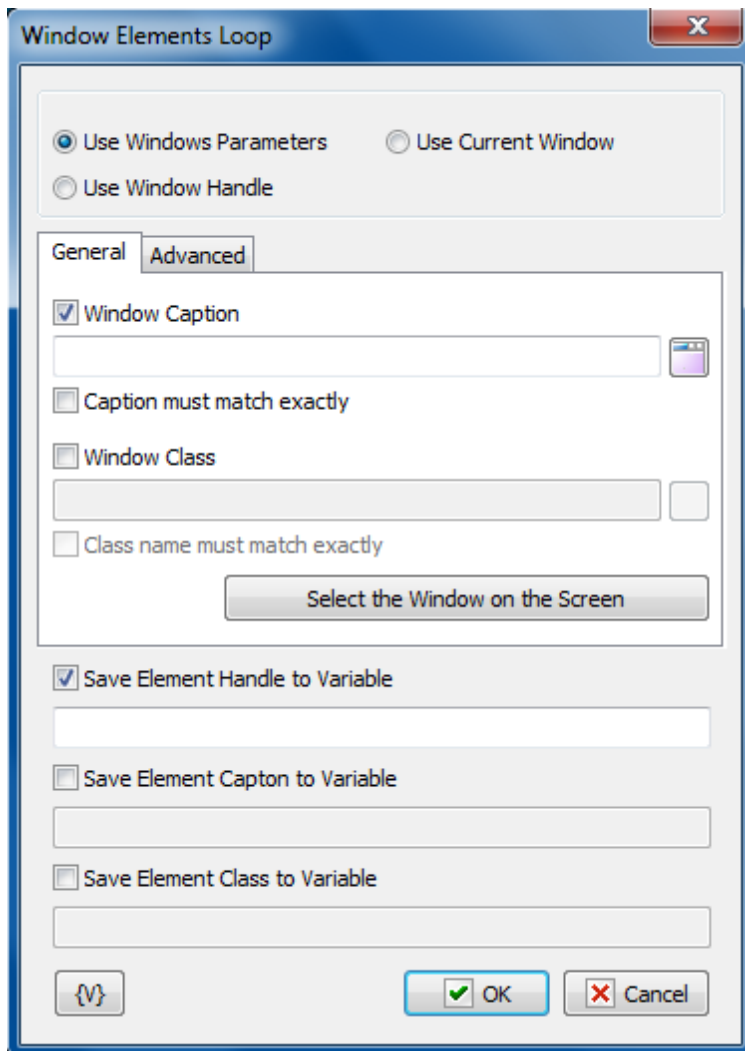

W - Specify a new width of the window. The usage of variables is allowed. The result of the expression must be an integer. Otherwise, the action uses default value, which is 640.

4.13.5 Window Elements Loop

This is a loop by window elements. Sometimes it is possible to extract and analyze some information from window elements. The loop enumerates all window elements registered in the system. When every iteration, you can save the characteristics of the current element into variables:

- Handle

- Caption
- Class

Window Parameters Mode

There are three options:

Use Window parameters - Use the Window Caption and the Window Class to look for the necessary window.

Use Window Handle - This is a search for a window by a handle. The handle can be got in the loop Window Loop, from the trigger Wait for Window or some other way.

Use current window - This is a current window in a moment of the executing of the action. This mode does not require any additional parameters.

Use Window parameters

Window Caption.

If you want to search for a window by means of its caption, switch on this checkbox and input the expected window caption. You can input only part of the caption. In this case the action will check availability of the input part in the window caption.

Caption Must Match Exactly.

If you need the exact coincidence of a window caption, switch on this checkbox.

Window Class.

If you want to search the window by a window class, switch on this checkbox and input the expected name of the window class. You can input only part of the name. In this case the action will check availability of the input line in the name of the window class.

Class Name Must Match Exactly.

If you need the exact coincidence of a window class, switch on this checkbox. Usually it is worthwhile to search by the whole class name, because a window class is permanent and does not change its value during the "life" of the window, unlike a caption.

Select Window on the Screen.

When pressing this button, you turn on the mechanism of selection a window on the screen. The window, which the mouse pointer points on, highlights with a red frame. Meanwhile, you can use the mouse to perform some actions. To select the necessary window, press *Ctrl*. To cancel - press *Esc*. When selecting a window, the fields Window Caption and Window Class are filled in automatically.

Window Handle.

Input the expression containing a window handle. This parameter is used for the mode Use Window Handle. A window handle is just a number, identifier of a window in a current session of system work.

Save Element Handle to Variable

If you want to save the value of the element handle, switch on this checkbox and input the value name in the entry field.

Save Element Caption to Variable

If you want to save the element caption, switch on this checkbox and input the value name in the entry field.

Save Element Class to Variable

If you want to save the class of the element, switch on this checkbox and input the value name in the entry field.

4.14 For Windows NT

4.14.1 Start Service

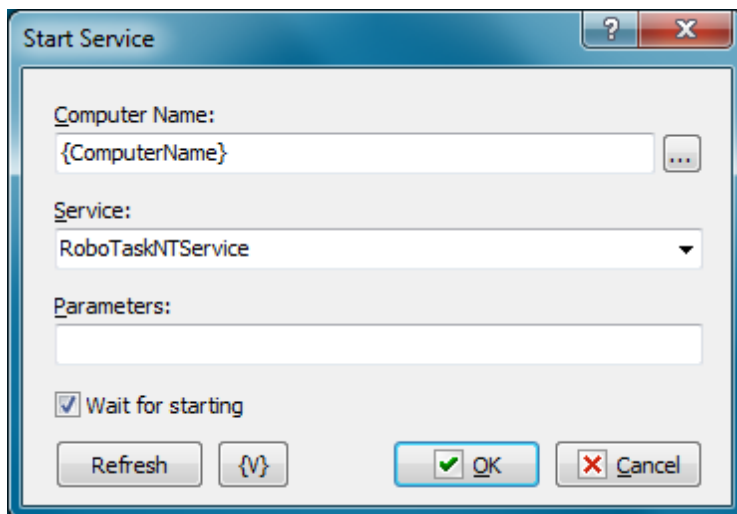

Important

- This action is not available on Windows 9x/Me.

Starts a service already installed on the local or remote NT server or workstation. A service is a special process that can be launched during operating system boot. The most important feature of a service is that you do not have to log on to the computer.

A service is started in the Local System account. You can start an existing service or a service that you created. Examples of services include FTP/HTTP servers, print spoolers, file sharing, and so forth.

Usually, Windows services do not have a user interface, but are managed through the Services applet of the Windows Control Panel, or a separate application or applet. Using the standard Services applet, you can start, stop, pause, or continue a previously installed service. The common way for a service to report a warning or error is recording an event into the system event log. You can review the log using the **Event Viewer** from **Administrative Tools** in Windows.

Computer Name

Enter the remote computer name. If you want to start a service on the local computer, use {ComputerName}. You can click the browse button to select a computer from the local area network.

Service

Select a service that you want to stop from the dropdown list. The items on this list depend on which services are present on the computer.

Parameters

Specify optional parameters for the service that you want to start.

Refresh

Click this button to refresh the **Service** list.

Variable

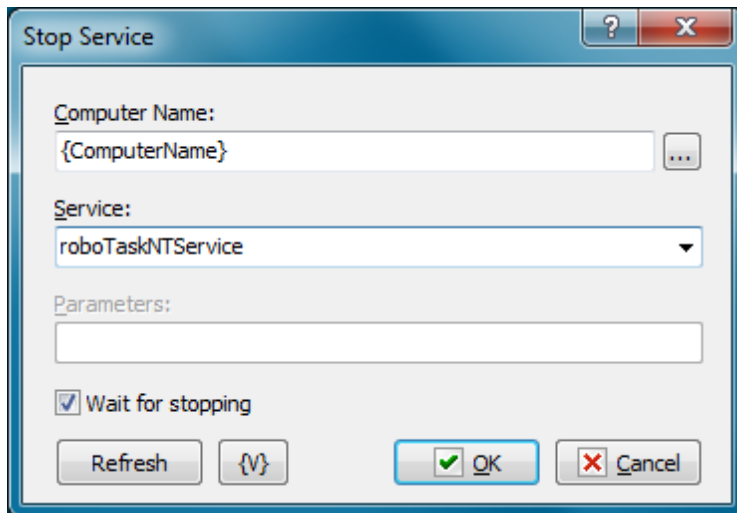

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.14.2 Stop Service

Important

- This action is not available on Windows 9x/Me.

Stops a service already installed and started on the local or remote server or workstation. For more information, see [Start Service](#).^[213]

Computer Name

Enter the remote computer name. If you want to start a service on the local computer, use {ComputerName}. You can click the browse button to select a computer from the local area network.

Service

Select a service that you want to stop from the dropdown list. The items on this list depend on which services are present on the local computer.

Refresh

Click this button to refresh the **Service** list.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.14.3 Service status

Important

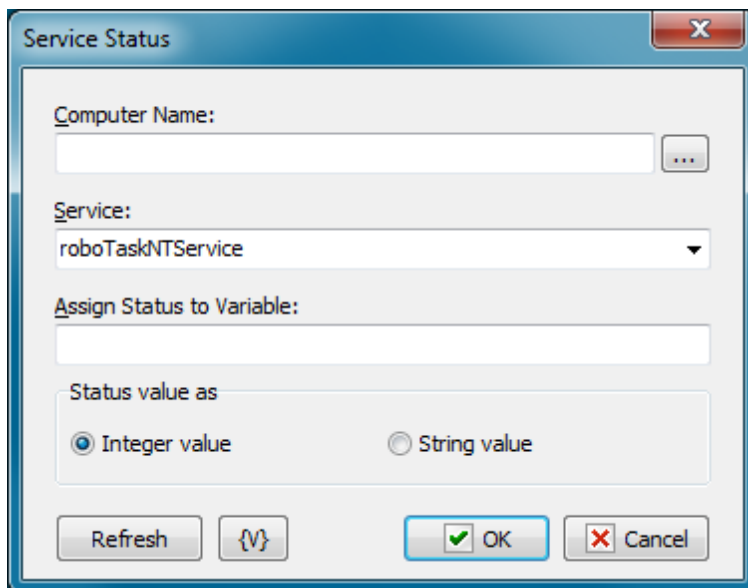

- This action is not available on Windows 9x/Me.

This action allows to read the status of a specified system service and to assign a value to a

variable.

The value of a service status can be assigned as a line or a number. The values correspond to the Microsoft documentation. There are 7 statuses:

- **SERVICE_STOPPED = 1** – The service is not running.
- **SERVICE_START_PENDING = 2** – The service is starting
- **SERVICE_STOP_PENDING = 3** – The service is stopping.
- **SERVICE_RUNNING = 4** – The service is running.
- **SERVICE_CONTINUE_PENDING = 5** – The service continue is pending.
- **SERVICE_PAUSE_PENDING = 6** – The service pause is pending.
- **SERVICE_PAUSED = 7** – The service is paused

Computer Name

Specify the computer name of a local network. The usage of variables is allowed. For example, {ComputerName}. If the name of computer is not specified (an empty line), a local computer is exploited.

Service

Specify the name of a service. The name can be typed or selected from a dropdown list. Usage of variables in the name of a service is allowed.

Assign Status to Variable

Assign the name of the variable where it is necessary to write the service status.

Status Value as

Specify the form of the value which is necessary to get.

- **Integer value** – the number from 1 to 7.
- **String value** – one of possible values:
 - SERVICE_STOPPED,
 - SERVICE_START_PENDING,
 - SERVICE_STOP_PENDING,

```
SERVICE_RUNNING,  
SERVICE_CONTINUE_PENDING,  
SERVICE_PAUSE_PENDING,  
SERVICE_PAUSED
```

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.14.4 Lock Workstation

This action submits a request to lock the workstation's display. Locking a workstation protects it from unauthorized use.

4.14.5 Run Program as User

This action allows running some application with rights of another user. It is especially useful for the system service mode because the application (a spawned process) is implemented by default with the rights of SYSTEM account. Sometimes it can cause some problems. For example, the launched application needs the access into the network with certain rights, or it needs some user settings.

**Program name**

Enter the program name into this field. You can type the text manually or select a file via dialog. You can also specify the document name in this field. In this case the document is opened by the default program according to the system settings.

Parameters

Enter the parameters of the program.

Current folder

The name of the current folder when the program is started. You can leave this field empty. In this case the folder is specified automatically.

Domain

The domain name. If you want to use the username of a local computer, write the dot symbol (.).

User Name

The name of user.

Password

The password of user.

Save Exit Code to Variable

If you want to save the exit code of the program, turn on this flag and write the variable name below. It is possible to save the code of the program completion only if the idle mode of the program completion is on.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.15 RoboTask Commands

4.15.1 Minimize RoboTask

Collapses the RoboTask window and displays the RoboTask icon on the Windows Taskbar. No specific settings are associated with this action.

This action is useful if you do not want RoboTask to appear on the computer while the task runs.

4.15.2 Restore RoboTask

Activates RoboTask and displays the RoboTask window on the computer screen. No specific settings are associated with this action.

This action is useful for system administrators who want to troubleshoot a process. For example, if a "critical error" occurs, you can use the **Disable Automation** action, trap an error message with the message box, and then use the **Restore RoboTask** action.

4.15.3 Exit RoboTask

Closes RoboTask. No specific settings are associated with this action.

4.15.4 Enable Automation

Enables task triggering. If task triggering is disabled, the tasks will not run automatically, i.e. all your tasks are disabled. You may run tasks only manually.

4.15.5 Disable Automation

Disables task triggering. If task triggering is disabled, the tasks will not run automatically, i.e. all your tasks are disabled. You may run tasks only manually.

4.15.6 Log Message

Records a message to the task's log. This action is a powerful tool for recording the results of actions when they occur in a log text file. This action is useful for system administrators who want to troubleshoot a process.

The log filename is based on the internal unique ID number of the task. Each task has an internal unique ID number and its filename is NNNNNNNN.tsk where NNNNNNNN is its ID number. The log file name is NNNNNNNN.log.

Important

- You can set options for logging on the [Advanced tab](#)^[45] of the **Add Task** dialog box or the **Edit Task** dialog box.

Message Text

Enter the text that you want to appear in the message.

Message Type

Select a type, such as **Information**, **Warning**, etc. The type determines the style of log message:

- Information** - a blue text and "i" icon appears.
- Warning** - an olive text and "!" icon.
- Error** - a red text and "X" icon.
- Neutral (user message)** - black text without icon. This kind of message can't be hidden even if you specify "Nothing" in "Log Level" parameter of the task.

Variable

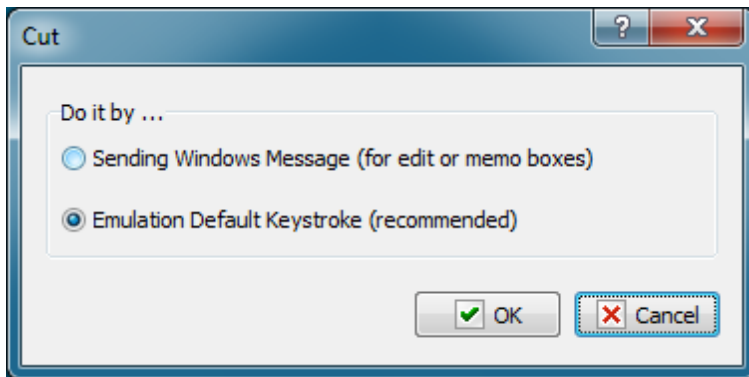

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then

click the {V} button.

4.16 Clipboard

4.16.1 Cut

Cuts the selected text fragment (image) into the system clipboard from the active Windows application.

Do it by...

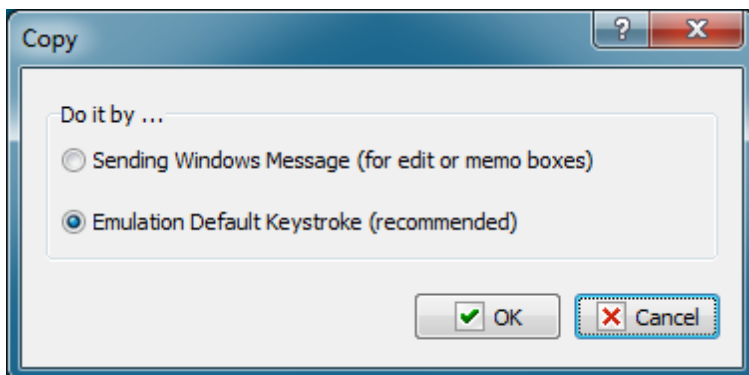

There are two ways to cut a fragment:

1. by sending a Windows message to the corresponding edit element
2. by emulating the key combination

It is recommended to use the second method because it is a universal mechanism for any application and any data type.

4.16.2 Copy

Copies the selected text fragment (image) into the system clipboard from the active Windows application.

Do it by...

There are two ways to copy a fragment:

1. by sending a Windows message to the corresponding edit element
2. by emulating the key combination

It is recommended to use the second method because it is a universal mechanism for any application and any data type.

4.16.3 Paste

Pastes the copied fragment from the system clipboard to the current Windows application.

**Do it by...**

There are two ways to paste a fragment:

1. by sending a Windows message to the corresponding edit element
2. by emulating the key combination

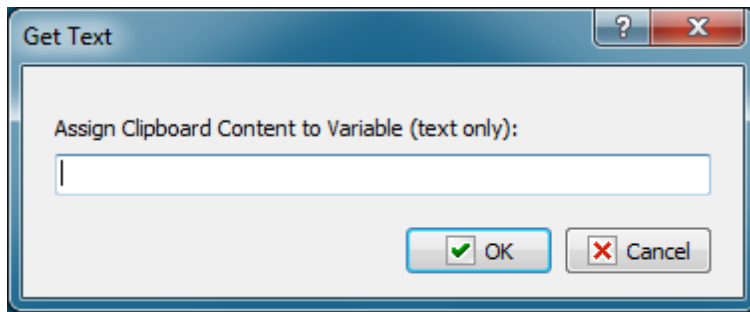

It is recommended to use the second method because it is a universal mechanism for any application and any data type.

4.16.4 Clear Clipboard

Clears the system clipboard. It has no parameters.

4.16.5 Get text

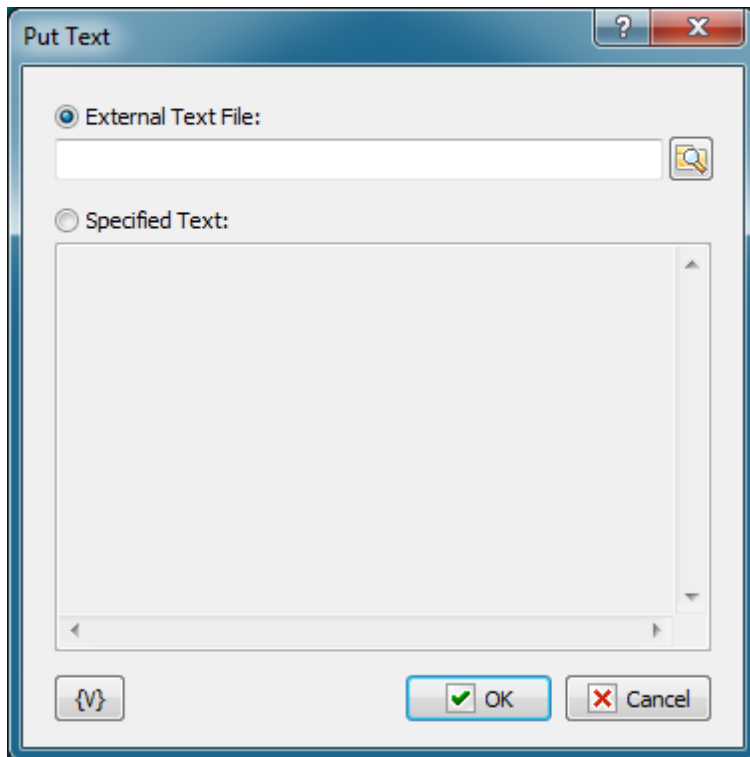

Assigns the text from the system clipboard to a variable. If the clipboard contains a graphic object or an object of some other type that cannot be converted into text, an empty string will be assigned to the variable.

**Assign Clipboard Content to variable**

Specify the variable the text from the system clipboard should be assigned to.

4.16.6 Put Text

Copies the specified text into the system clipboard. You can take text from a file or type it directly in the "Specified text" field. User and system RoboTask variables can be used.

**External Text File**

Specify the name of the file to take the text from.

Specified Text

Type the fragment that should be copied into the clipboard.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.17 Mouse

Actions for simulation of mouse movements and clicks.

4.17.1 Move to an object

Moves the mouse pointer to the specified object. You can select a control element in a window (button, menu, toolbar, etc.) or a window as an object.

The dialog box is titled "Move To Object" and contains the following fields and options:

- To Select Control:** A text box containing the text "Drag this text to desired control".
- Window Caption:** A text box.
- Window Caption Must Match Exactly
- Window Class:** A text box.
- Window Class Must Match Exactly
- Control Text:** A text box.
- Control Text Must Match Exactly
- Control Class:** A text box.
- Control Class Must Match Exactly
- Control Position:**
 - Left: 0
 - Top: 0
 - Right: 0
 - Bottom: 0
- Mouse Cursor Position:**
 - X: 0
 - Y: 0

Buttons at the bottom: {V}, OK, and Cancel.

To make editing this parameter more comfortable, you can drag the message "**Drag this text to desired control**" to the object you need. While you are moving the mouse pointer, elements

recognized by RoboTask are highlighted with a frame. After you release the left mouse button, all the parameters are specified automatically depending on the position of the mouse pointer. After that you can edit the parameter manually if necessary.

Window caption

Specify the window caption completely or any part of it. If the caption does not matter, leave the field blank.

Window caption must match exactly

If you need the caption to match exactly the specified caption, select this checkbox. If you do not need the exact match, you can specify any part of the window caption.

Window class

Specify the window class completely. If the class does not matter, leave the field blank.

Control Text

Specify the text of the window control element completely or partially.

Control Text must match exactly

If you need the control text to match exactly the specified text, select this checkbox. If you do not need the exact match, you can specify any part of the control element text.

Control class

Specify the control class completely. If the class does not matter, leave the field blank.

Control position

Specify the coordinates of the control element. The values are specified relatively to the window. The coordinates of the control are necessary in order to identify the control element because the window may contain several elements with the same Control Text and Control Class.

Mouse Cursor Position

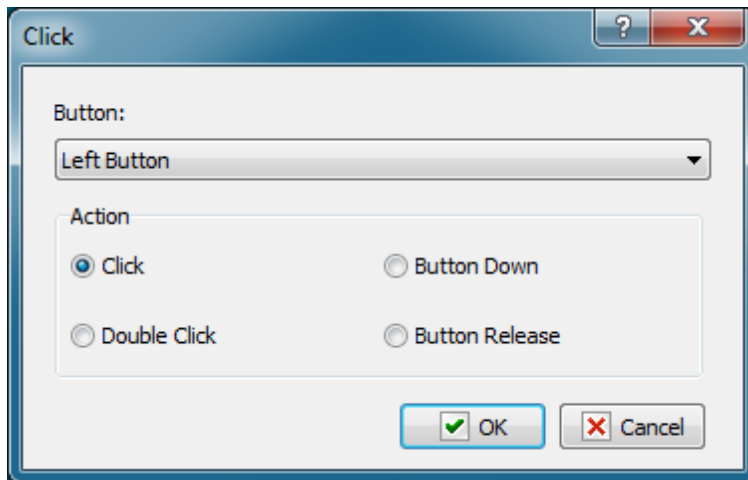

Specify the position of the mouse pointer relatively to the control element.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.17.2 Click

Emulates a mouse click in the current position.

Button

Select the mouse button:

- Left Button
- Right Button
- Middle Button.

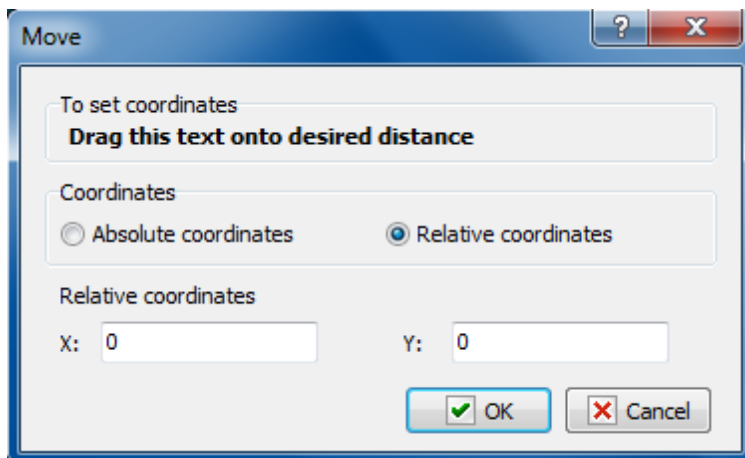

Action

Select the action. There are 4 variants to choose from:

- Click
- Double Click
- Button Down
- Button release

4.17.3 Move

Moves the mouse pointer the specified distance away from the current position or to the specified point.

Coordinates mode

Coordinates: absolute or relative.

- Absolute coordinate - the absolute coordinates of a point on the screen will be specified in the next parameter.
- Relative coordinates - the coordinates of a point on the screen relative to the current position of the mouse pointer will be specified in the next parameter.

Absolute or Relative coordinates

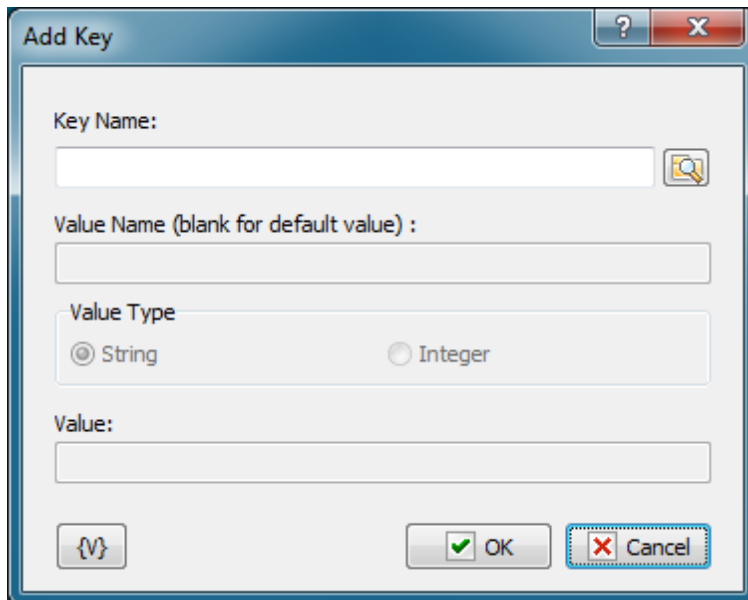

The coordinates of a point where the mouse pointer should be moved. The type of coordinates is determined by the previous parameter.

In order to set the coordinates interactively, you should drag the text in the upper part of the dialog box to the necessary point on the screen. The coordinate values will be specified automatically.

4.18 Registry

4.18.1 Add key

Adds a key (branch) to the registry.

Key Name

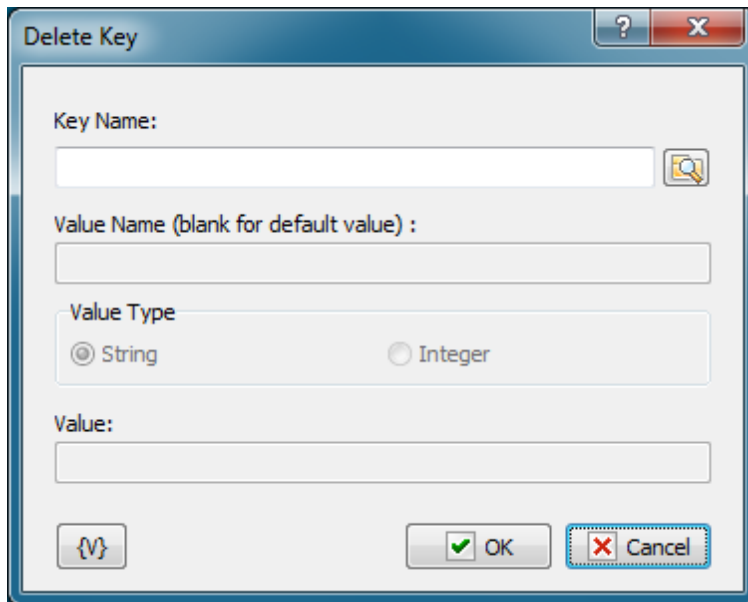

Name of the key to be added. You can use the dialog box to select the key interactively; to open it click the button to the right of the text box.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.2 Delete Key

Deletes the specified key (branch) from the registry. The specified key will be deleted together with all its subkeys and entries.

**Key Name**

Name of the key to be deleted. You can use the dialog box to select the key interactively; to open it click the button to the right of the text box.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.3 Rename Key

Renames the specified key (branch) of the registry

The image shows a 'Rename Key' dialog box with a blue title bar containing a question mark and a close button. The dialog contains the following fields and controls:

- Key Name:** A text input field with a magnifying glass icon to its right.
- Value Name (blank for default value):** A text input field.
- Value Type:** A group box containing two radio buttons: 'String' (selected) and 'Integer'.
- New Key Name:** A text input field.
- Buttons:** A '{V}' button, an 'OK' button with a green checkmark, and a 'Cancel' button with a red X.

Key Name

Name of the key to be renamed. You can use the dialog box to select the key interactively; to open it click the button to the right of the text box.

New Key Name

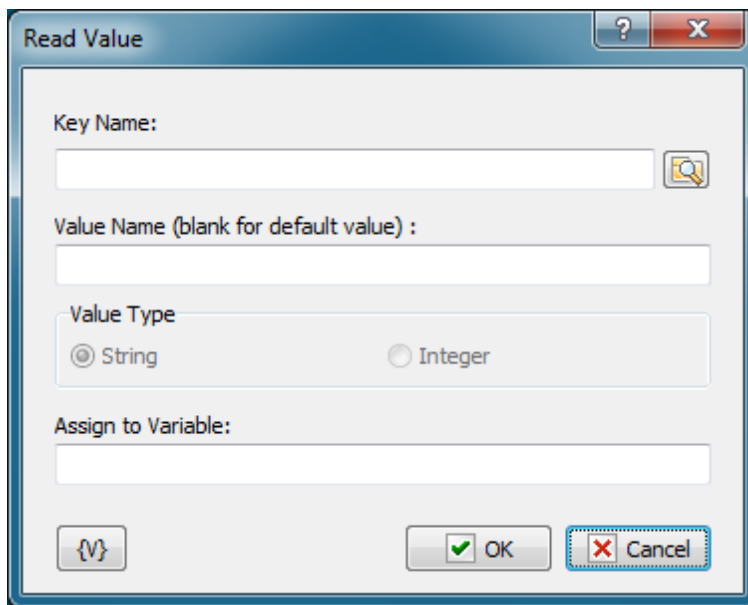

A new name that will be given to the specified key.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.4 Read Value

Read the specified value from the registry and assign it to the user variable. This action allows reading values of **String** and **Integer** types only.

Key Name

Full path to the value you want to read. You can use the dialog box to select the key and value interactively; to open it click the button to the right of the text box. When you click the OK button, the "Key Name" and "Value Name" fields will be filled, if you have selected the necessary value.

Value Name

Name of the value to be read. If you leave Value Name empty, RoboTask will read the default value of the key.

Assign to Variable

Name of the user variable that should be assigned the value we have read.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.5 Write Value

Write the value to the specified key in the registry. This action allows writing values of **String** and **Integer** types only.

**Key Name**

Full path to the value you'd like to write. You can use the dialog box to select the key and value interactively; to open it click the button to the right of the text box. When you click the OK button, the "Key Name" and "Value Name" fields will be filled, if you have selected the necessary value.

Value Name

Name of the value to be written.

Value Type

Select the type of value to be written: String or Integer.

Value

The value to be written.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.6 Delete value

Deletes the specified value from the registry.

**Key Name**

Full path to the value you'd like to delete. You can use the dialog box to select the key and value interactively; to open it click the button to the right of the text box. When you click the OK button, the "Key Name" and "Value Name" fields will be filled, if you have selected the necessary value.

Value Name

Name of the value to be deleted.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.7 Rename value

Renames the specified value in the registry.

**Key Name**

Full path to the value you'd like to rename. You can use the dialog box to select the key and value interactively; to open it click the button to the right of the text box. When you click the OK button, the "Key Name" and "Value Name" fields will be filled, if you have selected the necessary value.

Value Name

Name of the value to be renamed.

New Value Name

New name that will be assigned to the specified value.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.8 Export

Exports the specified registry branch to the specified file. The saved file has a format compatible with the **REGEDIT.EXE** system utility. This operation is useful when you make a backup copy of some information or move settings to another computer. You can easily import the export file using **REGEDIT** or the [Import](#)^[234] action of RoboTask.

Registry Key

The key (branch) of the registry that should be exported to a file. You can use the dialog box to select the key interactively; to open it click the button to the right of the text box.

File Name

Name of the file where information should be exported.

File Format

Choose the export file format.

- Registration file (current format) - current default format for the installed operating system. For Windows 2000 and higher the format is Unicode text.
- Win9/NT4 Registration File - old format that provides compatibility with Windows 9x/NT4. This format has a structure of a regular text file.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.18.9 Import

Imports the export file to the registry. The export file should be prepared with the **REGEDIT.EXE** system utility or the [Export](#)^[233] action.

**File Name.**

Name of the file to be imported.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.19 Network

4.19.1 Send Command

Allows you to send a string to a copy of RoboTask on another computer. This action works together with the ["Listener" triggering event](#) (355). The Listener event receives the string and can start some task according to its settings. Thus, you can synchronize several copies of RoboTask working on the local area network of your office or via the Intranet/Internet.

For example, it may be a command to pack IIS log files on the server and send the packed file by e-mail.

Host Name or IP Address

Specify the Host Name or IP address of the computer where you need to send the command. The Host Name can be either similar to *www.mydomain.com* for the Internet or just the name of the necessary computer for the local area network.

Port

Specify the port the command should be sent to. By default, the "Listener" listens to port 5254. The port number can be changed to any other number (see Plugin settings).

Access Password

Specify the password for connecting to remote RoboTask. If the Listener on remote RoboTask is configured to work without a password, leave this field blank.

Command

Specify the string (command) that should be sent to remote RoboTask. It can be any string. The "Listener" triggering event on the remote computer will analyze the string.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.19.2 Send Network Message

Sends a text message using a local network area (LAN) connection to the specified computer. For example, you can use this action to display a message every time you receive an e-mail from a special customer when you are logged into a different computer on your network and cannot check your e-mail.

Computer Name

Enter the name of the computer or domain name that the message should be sent to. When the "*" symbol (without quotes) is specified, the message is broadcast to every computer in the primary domain of the system.

Important

If the Windows Messenger service is not running on the target computer, the message will not be received.

Message Text

Specifies the text of the message to be sent.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.19.3 Network Plugin settings

The settings of the Network plugin are related to the "[Listener₃₅₅](#)" triggering event and set the global parameters of the "[Listener₃₅₅](#)".

Listener port

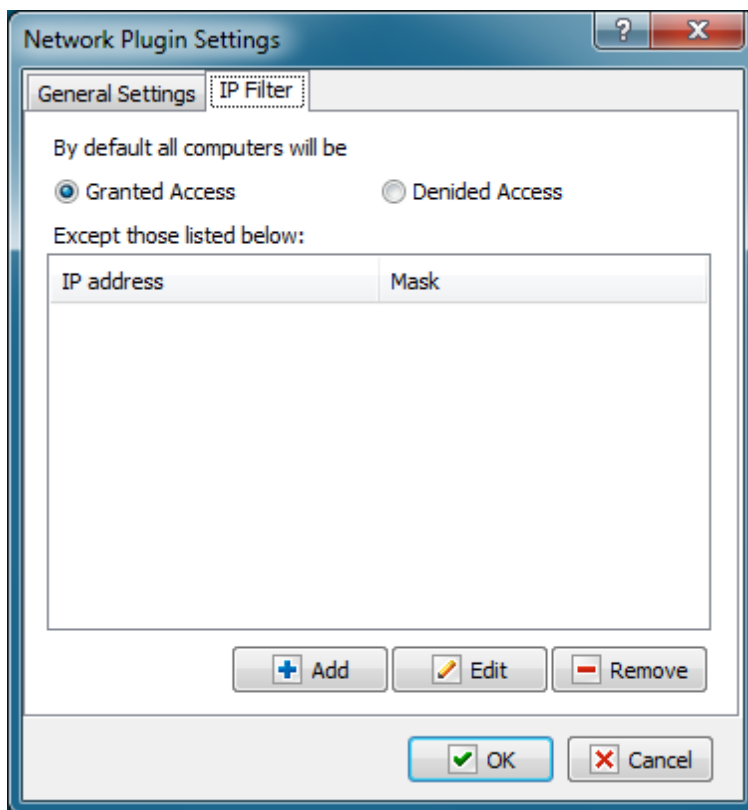

Specify the port the "Listener" will listen to. The default is 5254, but it can be changed for any other available port.

To Change Listener Access Password...

To change the access password for the Listener, specify the old password and enter the new password twice. By default, the password is empty, i.e. the access is granted without a password.

Encryption Required

Select this checkbox if you want to encrypt information when it is transferred between the computers. An 128-bit asymmetric encryption key is used for that. The key is generated randomly for each session.

**IP Filter**

You can use this tab to configure filtering requests by IP addresses. By default, the Listener is available for all IP addresses.

4.20 Email

This plugin contains email action which work with POP3 and IMAP protocols.

4.20.1 POP3 Open

Opens a connection with the POP3 server. This action should be performed before you perform the "[POP3 Mail Loop](#)^[240]", "[POP3 Download Email](#)^[241]" and "[POP3 Delete Email](#)^[242]" actions. There can be only one open connection with the POP3 server within a task. If you need to process several mail servers one by one, you should close the previous connection before opening the next one (see the "[POP3 close](#)^[240]" action).

**Host**

IP-address or Host Name of the POP3 server.

Port

Port of the POP3 server. By default it's 110.

Use SSL

Select this checkbox if you want to use SSL connection.

User Name

Name of the mailbox user.

Password

User password.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.20.2 POP3 Close

Closes the open connection with the POP3 server. It doesn't require any additional parameters. When a task is finished, the opened server connection closes automatically.

4.20.3 POP3 Mail Loop

Allows processing messages on the POP3 server one by one in a loop. This action also allows parsing main parameters of a message without downloading the complete message from the server. You can assign parameters of each message to a user variable and perform initial parse within a loop.

The screenshot shows a dialog box titled "POP3 Mail Loop". It contains a section titled "Assign Message Parameter to Variable" with the following options:

- Order number: [text input field]
- Subject: [text input field]
- Sender (FROM): [text input field]
- Recipient (TO): [text input field]
- Carbon Copy (CC): [text input field]
- Message Date: [text input field]
- Message Size (bytes): [text input field]

At the bottom right, there are "OK" and "Cancel" buttons.

Order Number

This loop parameter is compulsory as the current order number of a message serves as its identifier on the POP3 server. The numbering of messages starts with 1. The variable that contains the number of a message should be used in the loop in "[POP3 Download Email](#)^[241]" and "[POP3 Delete Email](#)^[242]" actions.

Subject

Optional parameter. Allows saving the message subject to a variable and parsing it in the loop.

Sender (FROM)

Optional parameter. Allows saving the sender address to a variable and using it within the loop.

Receipt (TO)

Optional parameter. Allows saving the recipient address to a variable as a string and using it within the loop.

Carbon Copy (CC)

Optional parameter. Allows saving the address of the recipient (or recipients) of a message copy to a variable as a string and use it within the loop.

Message Size

Optional parameter. Allows saving the message size in bytes to a variable and using it within the loop.

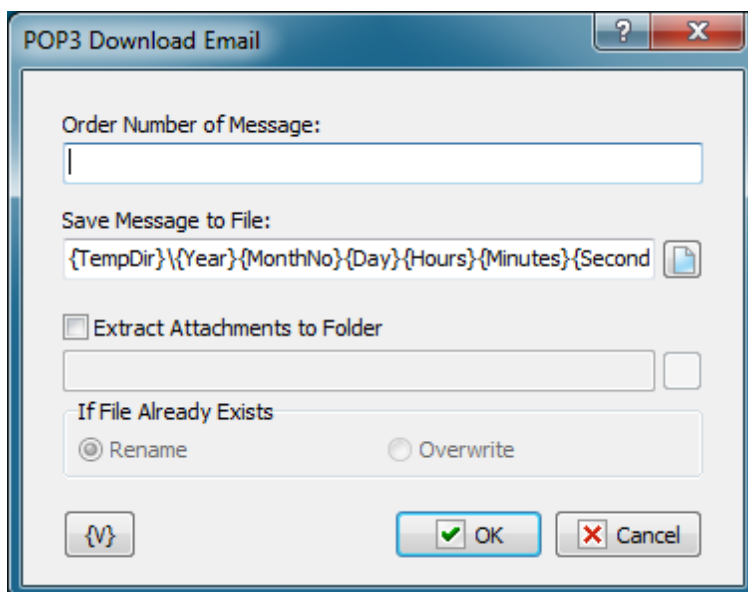

Note:

Addresses in the message can be written in form of:

- E-mail address only. For example:
john@yahoo.com
- Recipient's name and address. For example:
John Smith <john@yahoo.com>
- Several recipients separated with a semicolon. For example:
John Smith <john@yahoo.com>; Melissa Carver <melissa@hotmail.com>

4.20.4 POP3 Download Email

Receives a message from the POP3 server and saves it to a file.

Order Number of Message

Order number of the current message. It can be generated in the "POP3 mail loop" using a variable or you can set it manually. If the message number is invalid, an "Invalid number of message" error will occur when the action is carried out.

Save Message to File

Specify the name of file where the message should be saved. You can use variables to generate the file name. By default, the

```
{TempDir}\{Year}{MonthNo}{Day}{Hours}{Minutes}{Seconds}{mSeconds}.eml
```

string is specified. It provides a unique name and makes it more convenient to sort files by the time when the message was received.

Extract Attachments to Folder

When you receive a message, you can extract all attachments to separate files. To do it, you should specify a folder where all attachments should be extracted.

If File Already Exists

Specify an action that should be performed if the application file already exists.

- Rename - in this case a suffix with an order number will be added to the file name;
- Overwrite - the file will be saved with the original name and the old file will be overwritten.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.20.5 POP3 Delete Email

Deletes the email message from the POP3 server.

Order Number of Message

Order number of the message to be deleted. It can be generated in the "[POP3 mail loop](#)^[240]" using a variable or you can set it manually. If the message number is invalid, a "No such message" error will occur when is action is carried out.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.20.6 POP3 Messages Count

It is used to count the number and total size of messages on the incoming mail server (POP3 server). To use this action, you should establish a connection with the POP3 server using the ["POP3 Open" action](#)^[239]. You can save the number and total size of messages to custom variables to process them later in a task.

Assign Amount of Messages to Variable

Select this checkbox if you want to save the number of messages to a variable. You should enter the variable name into the field below.

Assign Total Size to Variable

Select this checkbox if you want to save the total size of messages (in bytes) to a variable. You should enter the variable name into the field below.

While editing the step, you should specify at least one variable.

4.20.7 Parse Email

Parses message in the file. It separates the message into its main parts:

- Message subject (the **SUBJECT** field);
- Sender (the **FROM** field);
- Recipient (the **TO** field);
- Recipient of a copy (the **CC** field);
- Message body (the text);
- Attachments.

File Name

Specify the filename of the message you want to parse. Such files usually have **EML** extension.

General tab

Subject

Specify the name of variable where the message subject should be saved.

Sender (FROM)

Specify the name of variable where the sender's address should be saved.

Recipient (TO)

Specify the name of variable where the recipient's address should be saved. This field can contain several addresses separated with a comma or a semicolon.

Carbon Copy (CC)

Specify the name of variable where the address of the recipient of a copy should be saved. This field can contain several addresses separated with a comma or a semicolon.

Message Text tab

**Assign Message Text to Variable**

Specify the variable where the message body should be saved.

Prefer

Specify the format that should be preferred if the message body contains both message formats. The message body can contain the following formats:

- Plain Text
- HTML Text

If the message body contains one format only, this message text will be assigned to the variable no matter what value the Prefer parameter has.

Attachments tab

Extract Attachments to Folder

Specify the folder where all attachments should be extracted.

If File Already Exists

Specify an action that should be performed if the specified folder already contains a file with the application name.

- Rename - in this case a suffix with an order number will be added to the file name;
- Overwrite - the application will be saved with the original name and the existing file will be overwritten.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Note:

Addresses in the message can be written in form of:

- E-mail address only. For example:
john@yahoo.com
- Recipient's name and address. For example:
John Smith <john@yahoo.com>

- Several recipients separated with a semicolon. For example:
John Smith <john@yahoo.com>; Melissa Carver <melissa@hotmail.com>

4.20.8 IMAP Open

The action opens the connection with the IMAP server. All actions with the IMAP server have to begin from the opening of the connection. Otherwise it is impossible to use the actions of the IMAP. It is possible to perform only one connection with the IMAP within one task. If you need to switch over another IMAP server within a task, at first, you should close the current connection (see the [IMAP Close](#)^[248]).

Server

The name or the IP address of a server.

Port

The number of a port for connection. On default, the port of the IMAP is 143 for a simple connection and 993 for the SSL connection.

Use SSL

Need for using the SSL (Secure Socket Layer)

User Name

A username for authentication.

Password

A password for authentication.

Select Mail Folder

Specify the folder which is necessary to be open after opening the connection. The folder can be specified manually or selected from the list pressing the button on the right of entry field. On default, the folder INBOX (the folder of incoming mail) is specified. The composition and names of folders depend on a mail server.

Almost all IMAP actions work with the current folder of a mail server. So it is necessary to select the current folder before to start working with IMAP messages.

4.20.9 IMAP Close

The action closes the previously opened connection. If the connection has not opened, the action is ignored.

The action does not need any additional settings.

4.20.10 IMAP Select Mail Folder

The action is designed for changing of the current folder of the mail server during execution of a task.

Select Mail Folder

Specify the name of a folder of the IMAP server. The folder name can be typed manually explicitly or using variables. Also the folder name can be selected from the list pressing the button on the right of entry field.

4.20.11 IMAP Mail loop

This action allows to process by cycle all messages from server. As with any another cycle, the group of cycle steps should be finished with the action End Loop. The IMAP Mail Loop uses a

current folder on the server. The folder can be set when the connection is opened or with the action IMAP Select Mail Folder.

In each iteration of the cycle you can save various characteristics of the current message into variables for processing by steps inside of the cycle.

IMAP Mail Loop

Assign Message Parameter to Variable

Order number:

Subject:

Sender (FROM):

Recipient (TO):

Carbon Copy (CC):

Message Date:

Message Size (bytes):

Message flags

{V}

Order Number

Specify the name of the variable into which it is necessary to save the ordinal number of the current message. Next actions with messages will execute according to the number of the message in the folder (for example, [IMAP Download Message](#)^[250], [IMAP Set Message Flags](#)^[252], etc).

Subject

To save the subject of the current message, switch on this checkbox and specify the variable name.

Sender (FROM)

To save the address and the sender name of the current message, switch on this checkbox and specify the variable name.

Recipient (TO)

To save the list of recipients of the current message, switch on this checkbox and specify the variable name.

Carbon Copy (CC)

To save the list of recipients of the carbon copy of the current message, switch on this checkbox and specify the variable name.

Message Date

To save the date and time of sending of the current message, switch on this checkbox and specify the variable name.

Message Size

To save the size in bytes of the current message, switch on this checkbox and specify the variable name.

Message Flags

To save flags (attributes) of the current message, switch on this checkbox and specify the variable name. Flags of the message will be saved as string. Every letter corresponds to existence of a flag of the message.

- A - Answered
- F - Flagged
- D - Deleted
- S - Seen
- T - Draft
- R - Recent

For example,

AS - means that the message is answered and seen.

R - recent message.

4.20.12 IMAP Download Message

The action permits to download a whole message from the server and save it into a file.

Order Number of the Message

An order number of a message. This number can be got in a cycle or specified explicitly. Numbers of messages begin from number 1.

Save Message to File

Specify the name of a file into which it is necessary to save the message. On default, it is proposed a file name based on a system date and time:

```
{TempDir}\{Year}{MonthNo}{Day}{Hours}{Minutes}{Seconds}{mSeconds}.eml
```

Such file name enables you to avoid name clashes. Also, you get a possibility to sort files according to the receiving time.

Extract Attachments to Folder

If you want to extract attached files, switch on this checkbox and specify the folder name.

If File Already Exists

Specify a necessary action if the file already exists when saving attachments:

- Rename
- Overwrite

Save attached file names to variable as comma separated

To save the list of attached file names into a variable, switch on this checkbox and specify the name of the variable.

4.20.13 IMAP Get Message Flags

The action enables to get message flags according to their ordinal number and save them into a variable. The message flags are saved as a line. Each letter corresponds to existence of the flag of the message.

- A - Answered
- F - Flagged
- D - Deleted
- S - Seen
- T - Draft
- R - Recent

Order Number of the Message

An order number of a message. This number can be got in a cycle or specified explicitly. Numbers of messages begin from number 1.

Save Flags to Variable

Specify the name of the variable into which it is necessary to save message flags.

4.20.14 IMAP Set Message Flags

Sets up message flags according to the number in the current folder. Flags are set by means of checkboxes. Notice that each checkbox has 3 statuses:

- Off. This means that the flag should be resetted (cleared).
- On. This means that the flag should be set.
- Intermediate status. This means that the flag should be left unchanged.

Message Number

The ordinal number of the message in the current server folder.

Message Flags

Set up new message flags by means of checkboxes. There are 6 checkboxes which correspond to the message flags:

- Answered
- Flagged
- Deleted
- Seen
- Draft
- Recent

Notice, that to mark the message for deletion, it is enough to mark it with the flag Deleted. After all necessary messages are marked, the action IMAP Delete Marked Messages needs to be performed.

4.20.15 IMAP Delete Marked Messages

Performs physical deletion of all messages which are marked with the flag Deleted (see IMAP Set Message Flags). The action performs for messages in the current folder and does not require additional parameters.

4.20.16 IMAP Copy Message

The action performs copying of a message from the current folder into other folder of the server.

Message Number

The number of a message in the current folder. The numbers begin from 1. It is allowed to use variables.

Copy Message to this Folder

Input the name of the destination folder. The folder name can be input manually or selected from the list pushing the selection button on the right of the field. Also it is allowed to use variables.

Note:

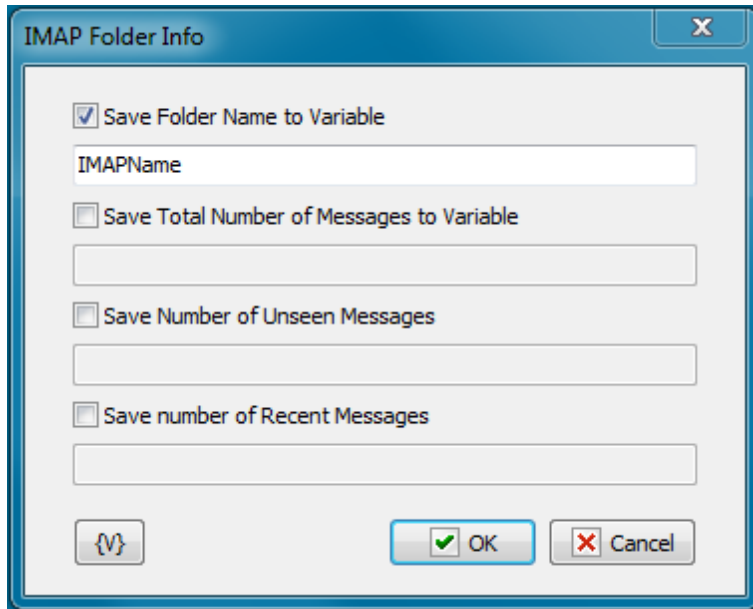

If you want to MOVE the message into another folder you have to copy the message and then mark it as DELETED (see [IMAP Set Message Flags](#)^[252] action). Also you can put the [IMAP Delete Marked Messages](#)^[253] after moving all necessary messages.

4.20.17 IMAP Folder Info

The action enables to read parameters of the current folder and to save their values into variables for the next processing.

The folder parameters which can be extract:

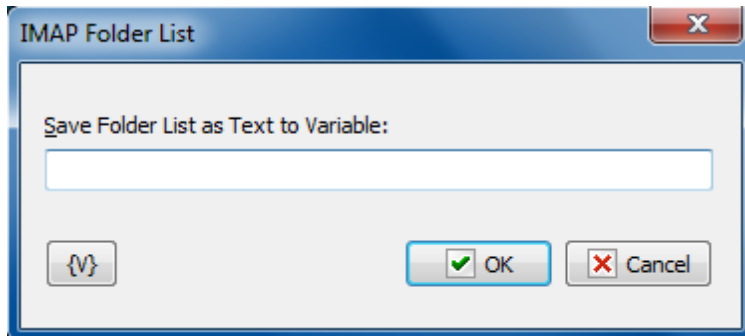

- The folder name
- Amount of messages
- Amount of not shown messages
- Amount of resent messages

To extract the parameter value, it is necessary to switch on the appropriate checkbox and to input the variable name.

4.20.18 IMAP Folder List

This action saves the folder list of an open IMAP server as a text into a variable. Every folder name is on the new line. You can process the text line by line, for example. In the loop Text Loop.

Save Folder List as Text to Variable

Input the name of the variable into which you need to save the folder list.

4.21 Strings

4.21.1 STR Replace

This action finds and replaces the specified string with the one you need. There are three replacement modes:

- All Entries;
- First entry;
- Last Entry.

The result is assigned to a user variable.

Source String

The source string to search and replace in. It is possible to use variables.

Find Substring

The substring that should be found and replaced. It is possible to use variables.

Replacement

The substring to replace the found substring with. It is possible to use variables.

Replace mode

Replacement mode. 3 options are possible:

- All Entries – all found substrings will be replaced;
- First Entry – only the first found substring will be replaced;
- Last Entry – only the last found substring will be replaced;

Assign Result to Variable

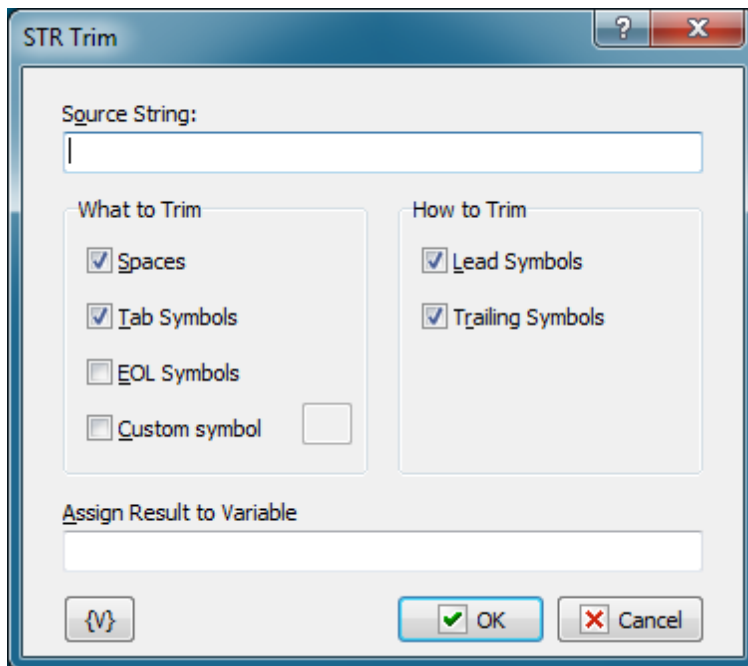

The name of the variable the result of the action will be assigned to. It is impossible to use macros with variables

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.2 STR Trim

This action allows you to trim unnecessary characters at the beginning and at the end of the string.

Source String

The source string to perform the action in. It is possible to use variables.

What to Trim

The characters to trim.

- Spaces
- Tabs
- EOL symbols – end-of-line characters
- Custom symbol - you may specify any symbol

You can select the options independently of each other. It is enough to select at least one option.

How to Trim

2 options are possible:

- Lead Symbols
- Trailing Symbols

You can select the options independently of each other. It is enough to select at least one option.

Assign Result to Variable

The name of the variable the result of the action will be assigned to. It is impossible to use macros with variables

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.3 STR Delete

The action deletes the specified number of characters from the specified position in the source string.

Source String

The source string to delete the characters in. It is possible to use variables.

From Position

Specify the position to start deleting characters from. The value must be a positive integer. The positions of characters in a string start from 1. It is possible to use variables.

Amount of Chars

Specify the number of characters that should be deleted starting from the specified position. The value must be a positive integer. It is possible to use variables.

Assign Result to Variable

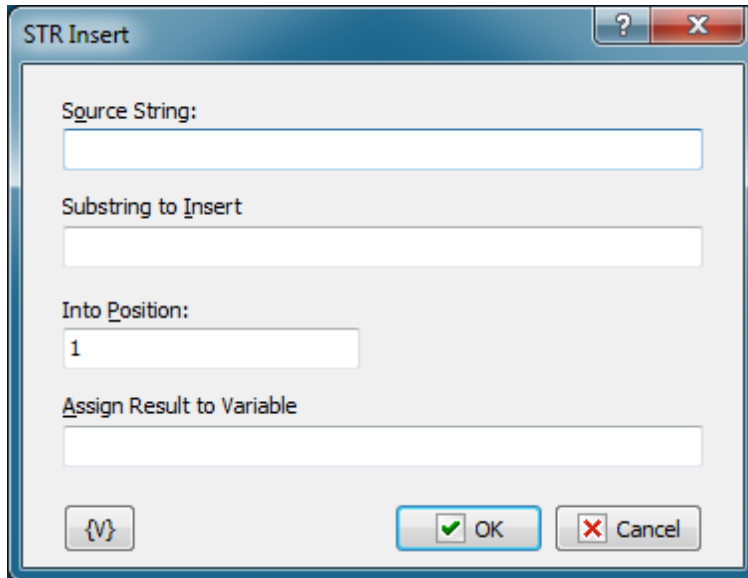

Specify the name of the variable the result of the action will be assigned to. It is impossible to use macros with variables

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.4 STR Insert

The action inserts a substring into the specified position in the source string.

**Source String**

The source string to insert the substring to. It is possible to use variables.

Substring to Insert

The substring to insert to the source string. It is possible to use variables.

Into Position

Insertion position. The positions of characters in a string start from 1. If you specify a position less than 1, the substring will be inserted at the beginning. If the position of the insertion is greater than the number of characters in the source string, the substring will be added to the end of the source string. It is possible to use variables.

Assign Result to Variable

The name of the variable the result of the action will be assigned to. It is impossible to use macros with variables

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.5 STR Extract

The action cuts the specified number of characters from the string starting from the specified position. The cut substring is assigned to a user variable.

**Source String**

The source string to cut the substring from. It is possible to use variables.

From Position

Specify the position to start cutting characters from. The value must be a positive integer. The positions of characters in a string start from 1. If the position is less than 1, the substring will be cut from the beginning of the source string. It is possible to use variables.

Amount of Chars

Specify the number of characters that should be extracted starting from the specified position. The value must be a positive integer. It is possible to use variables.

Assign Result to Variable

The name of the variable the result of the action will be assigned to. It is impossible to use macros with variables

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.6 STR Pos

The action determines the position of the found substring in the source string. If the substring is found, the result will be positive. Otherwise, the result is 0.

Source String

The source string to find the substring in. It is possible to use variables.

Substring to Search

The substring to search for. It is possible to use variables.

From Position

The position to start searching from. Position 1 corresponds to the beginning of the string. It is possible to use variables.

Assign Result to Variable

The name of the variable the result of the action will be assigned to. The result is an integer. If the substring is found, the value is greater than 0. Otherwise, it is 0. It is impossible to use macros with variables.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.7 STR Between

This action cuts a substring that is enclosed by two sequences of characters out of the source string.

Suppose we have the following string:

```
<h3><b>Another news - at last week</b></h3>
```

We need to cut the meaningful string out, i.e. the string between the HTML tags. It is easy with the STR Between action. To do it, you should create the limiting sequences of characters:
Start - **<h3>**

End - **</h3>**

The action cuts the string between the start and end marks out and assigns the result to a custom variable for further processing. If at least one mark is not found in the source string, the action will return an empty string.

Source String

Specify the source string to be processed. It is possible to use variables.

Begin Mark

The start mark of the substring. It is possible to use variables

End Mark

The end mark of the substring. It is possible to use variables

Case Sensitive

You can make the search for the substring case-sensitive. By default, the search for the substring is case-insensitive.

Start Position

The position of the character the search will be started from. Number 1 corresponds to the beginning of the string. If the number is greater than the length of the string, the action will return an empty result. It is possible to use variables.

Assign Result to Variable

Enter the name of the custom variable to assign the result to.

Save Next Start Position to Variable

If necessary, you can specify the name of the variable you can assign the start position for the next substring search to. If we reach the end of the string, the next start position will be equal to 0.

It is necessary, for example, in order to get all substrings meeting the specified criteria in the source string.

Suppose we need to get all substrings enclosed by parentheses in the following string:

```
Just (a few minutes) with RoboTask will give you (plenty of ideas) of how you can  
(increase) your productivity
```

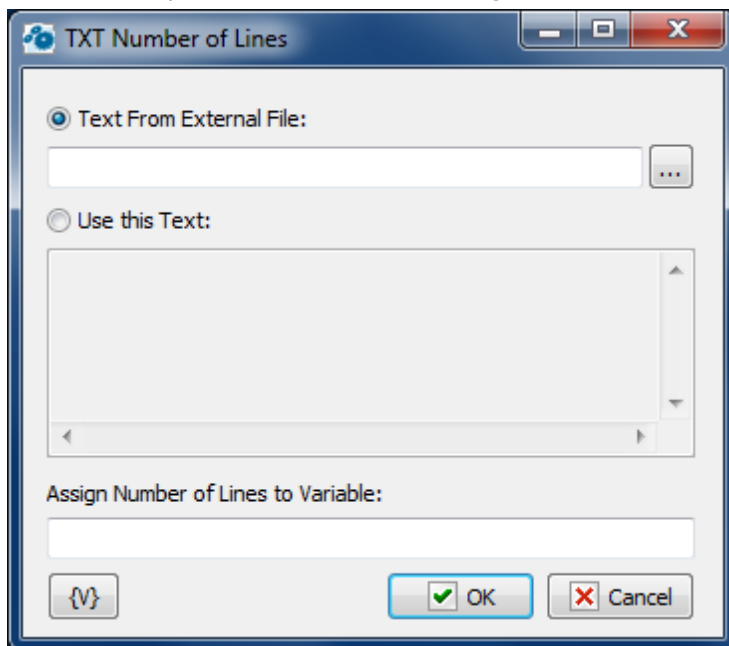

You can easily do it using a loop. See the following example: **"[DEMO] STR Between - extract all entries"**

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.8 TXT Number of Lines

The action is intended to count the number of lines in a text. It allows to count the number of lines in a specified file as well as in a specified text with variables. The action assigns the result to a specified variable for using it in the following steps.

Text from External File

Specify the file name where it is necessary to count the number of lines. It is possible to select the name using the dialog of file selection. Using variables in the file name is possible.

Use this Text

You can set a text in the editing field explicitly. The text can also contain variables.

Assign Number of Lines to Variable

Specify the name of a variable where the number of lines is to be assigned.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.9 TXT Extract Line

This action allows extracting a line by number from a text. The number has to be specified from 1 to the quantity of lines in a text. If the number is incorrect, the action will return an empty line. The action assigns the specified line to a variable for using it in the following steps.

Text from External File

Specify the file name where it is necessary to count the number of lines. It is possible to select the name using the dialog of file selection. Using variables in the file name is possible.

Use this Text

You can set a text in the editing field explicitly. The text can also contain variables.

Line Number

Specify the number of a line which is necessary to extract from a text. Using variables is possible. If non-numeric value is specified, the action generates a run-time error.

Assign Extracted Line to Variable

Specify the name of the variable where the demanded line will be assigned.

Variable

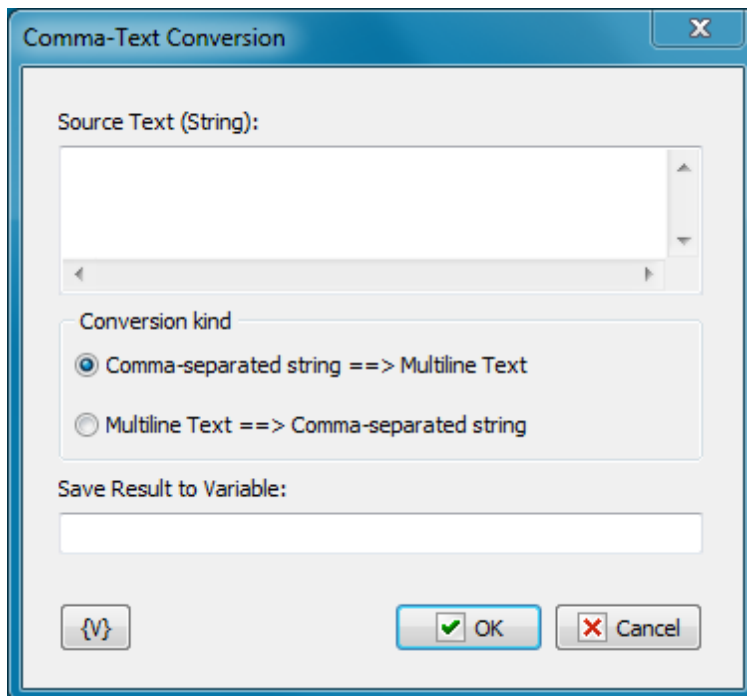

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.21.10 TXT Comma-Text Conversion

This action is designed for conversion of a comma-separated string in a multiline text and vice versa.

Often data for machine processing is given as comma-separated string. At the same time a multiline text is easier for processing.

- Processing of strings in the cycle (Text Loop)
- Calculation of quantity of strings and extraction of a string by its number.
- etc.

Source Text (string)

Specify a source text or a comma-separated string for conversion.

Conversion kind

Select one of two conversion options

- Comma-Separated String ==> Multiline Text
- Multiline Text ==> Comma-Separated String

Save Result into Variable

Input the name of the variable into which you need to save the result of the conversion.

4.22 Basic

The **Basic** plugin is not included in the main installation package. You can download it additionally from <http://www.robotask.com/downloads/>.

4.22.1 Evaluate

Allows you to make calculations using the functions of mathematical operations and BASIC functions. The result is assigned to a user variable. This action is convenient when you need to make some small calculations without writing a Basic script.

Expression to Evaluate

Mathematical expression. The result can be of any type. For more details on expression syntax see description of BASIC language.

For example:

```
{TotalSize}/{FileCount}
Left(Right("{DateTime}",8),2)
```

Assign Result to Variable

Specify the variable the result should be assigned to.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Test

Click this button to ensure that the parameters for the current action work.

4.22.2 Basic script

It is a universal tool allowing you to execute scripts written in BASIC. Scripts can be virtually as complicated as you need. You can use such a script to access the RoboTaskApp COM object allowing you to access service functions of RoboTask, as well as other tasks. The description of the RoboTaskApp object is given below.

See additional information about the BASIC language in the BASIC help.

**Script source**

You can select the script storage method

- **Internal** - the script is stored in the task file in this case. This storage method is good for small scripts consisting of one or several procedures.
- **External Script** - the script is stored in a separate file. This storage method is good for complex subroutines consisting of several modules (see the keyword "uses" or "include" in the Basic help).

4.23 Web Documents

Plugin for working with web pages and web forms.

The plugin contains next actions:

[Fill Web Form](#)^[268];

[Wait for done](#)^[273];

[Web Page Information](#)^[278].

4.23.1 Fill Web Form

This action is destined for automation of filling web forms. Of course you can automate filling forms by "[Send Keystrokes](#)^[72]" and [mouse actions](#)^[224]. But unfortunately, this is much more difficult and unreliable, because RoboTask tries to influence your external application (your web browser) and can't control the reaction of the program to this influence completely.

"Fill Web Form" works differently. It loads the web page with a form under its control, waits for a full loading of the page and can fill a form on the inside. If auto-submit is performed, the action will be waiting for the end of the resultant page loading. Thereby it is guaranteed that the task can pass to the next step only after the end of the page loading.

After filling the form you can keep on interactive working with the site (see the action "[Wait For Done](#)^[273]") or close embedded Web browser.

The embedded web browser will be in of memory only during the work of a task. RoboTask will unload the object "embedded web browser" out of memory after the end of the task or in case an error appears.

General options

Fill Web Form

General options Autologon Auto Download File

Web Address (Empty for Current Form):

Load

Form to Fill:

You can fill up the form manually in embegged web browser and press button "Fill the List" -->

Fill the List

Form Filling Parameters:

Field name	N...	Field Type	Value

Autosubmit the Form

Click the Form Button

Keep Page for Next Actions

Hide Browser Window

OK Cancel

Web Address

Fill the web address of the page which needs loading. You can leave its field empty if you want to use the page which was loaded in the previous steps of the task. You can use variables.

On the right of the field there is the "Load" button. When you press it, the specified address will be opened in embedded web browser. After loading, there will be available the lists of forms, elements of a form and the lists of item values kind of "Select" and "Multiselect".

After the form loading into embedded web browser, all the visual elements of all forms at the page will have pop-up hints, where the next information will be specified:

- The name of a form
- The name of the field
- The common ordinal number of the field
- The type of the edit field

Form to Fill

The name of a form that you should fill. You can choose the name of a form from the drop-down list if you have loaded the page. You can also fill the name of the form manually. You can use variables.

There may be nameless forms on any pages. This is allowed by the HTML standard. In this case you can refer to the form according to an ordinal number in the list beginning from 0. In other words, the first form on the page will have the number 0, the second – 1, etc.

Fill the form

After loading the web page in embedded web browser, you can fill the necessary form on the page manually, then press the button "Fill the List". After confirmation, an editor will fill the field list from the chosen form.

After auto filling, you can edit the list manually: to add/delete elements or to change the elements that are existing.

Form Filling Parameters

A parameter list for a form. You can edit a list using buttons on the right. (See ["Add or Edit Web Form Parameter dialog"](#)^[272])

Autosubmit the Form

Turn on this checkbox if you want to submit a form automatically after filling. By default this parameter is turned on. If auto-submit is performed, an action will be waiting for finishing loading of the resultant page. Otherwise, you need to submit manually. In this case the next step of the task must be the action "Wait for Done" and then performing necessary actions manually. This can be useful if you need to input the value CAPTCHA before pressing the button "Submit" or to perform any other interactive actions.

Click the Form Button

To reproduce a button click on a web form, switch on this checkbox and select the button name from dropdown list or input it by hand.

Keep Page for Next Actions

Turn on this checkbox if you want to leave the resultant page for interactive work or for filling the next form. By default, this parameter is off. If this parameter is turned off, embedded web browser will be closed immediately after the end of the step.

Hide Browser Window

To ensure hidden work of the web browser window, switch on this checkbox. In this case the browser window is not visible on the screen.

Autologon

You can specify parameters of automatic authorization on this tab if WEB browser demands authorization for access to resource. This way of automatic authorization works only with Basic and Digest authorization modes. In this case browser demands to input a user name and a password into the pop-up system window. If you specified parameters of automatic authorization, the action puts the parameters automatically when browser demands authorization.

If it is necessary to input the authorization parameters into the form on a page, then it is the so-called cookie authorization. In this case you should use the automatic filling of WEB form.

The image shows a screenshot of a dialog box titled "Fill Web Form". The dialog has three tabs: "General options", "Autologon", and "Auto Download File". The "Autologon" tab is selected. Inside the dialog, there is a checkbox labeled "Enable Autologon" which is currently unchecked. Below this is a section titled "Login Parameters" containing two text input fields: "User Name :" and "Password :". At the bottom of the dialog, there is a text box with the following text: "Autologon feature with with Basic and Negotiate authorization. In this case web browser requests login parameters in popup dialog." At the very bottom of the dialog, there are three buttons: a button with a refresh icon, an "OK" button with a green checkmark, and a "Cancel" button with a red X.

Enable Autologon

It switches on the mode of automatic authorization using the specified User Name and Password. If the mode of automatic authorization is switched off, authorization occurs in a usual mode.

User name

A name of a user for authorization. Variables can be used.

Password

A password for authorization. Variables can be used.

Auto Download file

On this tab you can tune parameters of automatic file downloading from a site.

For example, this mode is useful for automation of file downloading from the zone protected by a password. It occurs approximately in such a way:

- You specify URL of a file.
- When you try downloading a file, the browser demands a password or redirects the request to the Login form subject to the authorization mode on the site.
- When a password is requested, it is necessary to set up Autologon. When the request is redirected to a form, you should perform the automatic filling of the form.
- After you input parameters of authorization, the file will be downloaded into the specified folder automatically.

**Enable Auto-download File**

It switches on the mode of automatic file downloading. If auto-download is off, downloading occurs in a usual mode requesting a folder and a file name.

Download Folder

Specify the folder in which the file will be downloaded automatically. It will be downloaded with the file name by default.

Overwrite File If Exists.

Switch on this checkbox if you want the action to overwrite a file, on condition there is a file with the same name in this folder. Otherwise the downloaded file will be renamed.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.23.1.1 Add or Edit Web Form Parameter dialog

Every parameter has four components for filling a form:

- Field name
- Field number
- Field Type
- Field value

Field Name

The name of the field that needs filling with a new value. You can input the name manually or choose it from dropdown list. Pay attention that the dropdown list will be filled only if you have loaded the web-form into embedded web browser.

Field Number

HTML standard allows of presence of several fields with the same name on a form. In this case, you need to specify the field number among the fields with the same name. Numeration

begins from 0. If fields on the form have unique names the number of each field will be 0.

Field Type

For right filling a field you need to specify its type. It is supported seven types in all;

- **Edit** – a simple single-line string field;
- **Memo** – multi-line text;
- **Select** – choice one option among the several from the proposed list;
- **Multiselect** – choice several options from the proposed list;
- **Check** – usually checkbox;
- **Radio** – radio button;
- **Hidden** – a hidden field of a form. This field is recommended to change only if you imagine clear, why you need to change values. As a rule, hidden fields are necessary for keeping various service information of a field.

Field Type will take the necessary value automatically when you choose the name of a field from a list (see the Field Name)

Editing value of a field

View of a field value editor changes subject to its type

- **Edit** – input a field value. You can use variables.
- **Memo** – input .a text in the field. You can use variables
- **Select** – input a line (or part of a line), that need doing chosen. You can use variables. If the form is loaded, you can choose the necessary line from a dropdown list.
- **Multiselect** – input lines (or parts of lines), that need doing chosen. You can fill the list using available options pressing the button "Fill Up by Available Options", and then delete the needless.
- **Check** – choose one value form two – Unchecked and Checked
- **Radio** – choose one value form two – Unchecked and Checked
- **Hidden** – input a field value. You can use variables.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.23.2 Wait for Done

This action is destined for free work with a web page. The action stops work of task until a user presses the button "Done" in the window Embedded Web Browser.

During of work of the action, buttons of navigation "Go Back" and "Go Forward" and button "Done" appear in the window Embedded Web Browser. The action is useful when the

interactive interference of a user is needed. For example, to fill the value of CAPTCHA. Any interactive work with a web page is allowed: click on links, filling and submit of forms, etc. After finishing the interactive work it is necessary to press the button "Done".

General options

Web Address

Fill the web address of the page that need loading. You can leave a field empty if you want to use the current page that has been loaded during the previous steps of the task. You can use variables.

Keep Page for Next Actions

Turn this checkbox on if you want to leave the resultant page for interactive work or for filling the next form. By default, this parameter is turned off. If this parameter is turned off, Embedded Web Browser will be closed immediately after the finish of work of a step.

Autologon

Enable Autologon

It switches on the mode of automatic authorization using the specified User Name and Password. If the mode of automatic authorization is switched off, authorization occurs in a usual mode.

User name

A name of a user for authorization. Variables can be used.

Password

A password for authorization. Variables can be used.

Auto Download file

Enable Auto-download File

It switches on the mode of automatic file downloading. If auto-download is off, downloading occurs in a usual mode requesting a folder and a file name.

Download Folder

Specify the folder in which the file will be downloaded automatically. It will be downloaded with the file name by default.

Overwrite File If Exists.

Switch on this checkbox if you want the action to overwrite a file, on condition there is a file with the same name in this folder. Otherwise the downloaded file will be renamed.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.23.3 Web Page information

This action simulates a visit to the specified web page by means of built-in web browser. If the address of a page is not specified, the action uses the current page which has been loaded in the previous steps. Also the action allows to extract the following information from the web page:

- **HTML code** – the source code of the page as HTML text.
- **Text** – the plain text of the page without HTML tags
- **Links** – the list of links as a text on the page : one link per line.

The extracted information can be assigned to variables for the following processing.

General options

Web Address

The address of a web page which is necessary to download. If the address is not specified, the action uses the current page which has been downloaded in the previous steps.

Keep the Page for Next Actions

If you need the downloaded page to be available in the following steps, switch on this parameter. Otherwise, the page will be deleted from the memory immediately after performing this action.

Hide Browser Window

To ensure hidden work of the web browser window, switch on this checkbox. In this case the browser window is not visible on the screen.

Get HTML Code of the Page

Switch on this checkbox if you want to get an HTML code.

Assign HTML code to Variable

Specify the name of the variable in which the HTML code will be assigned.

From Body Section Only (HTML code)

If the information of the HTML page title is not needed, switch on this flag. In this case, the action will process only the section `<body>...</body>`.

Get Text of the Page

Switch on this checkbox if you want to get extract the text from the page. The action extracts the text only, without any HTML tags.

Assign Text to Variable

Specify the name of the variable in which the extracted text will be assigned.

From Body Section Only (text)

If the information of the page title is not needed, switch on this flag. In this case, the action will process the section `<body></body>` only.

Get Links from the Page

If you want to get a list of links on the page, switch on this checkbox and specify the name of the variable in which you need to assign the received list. The action extracts the list of links as a text, one link per line. Then you can process this list in a loop (e.g. in Text Loop).

Autologon

Enable Autologon

It switches on the mode of automatic authorization using the specified User Name and Password. If the mode of automatic authorization is switched off, authorization occurs in a usual mode.

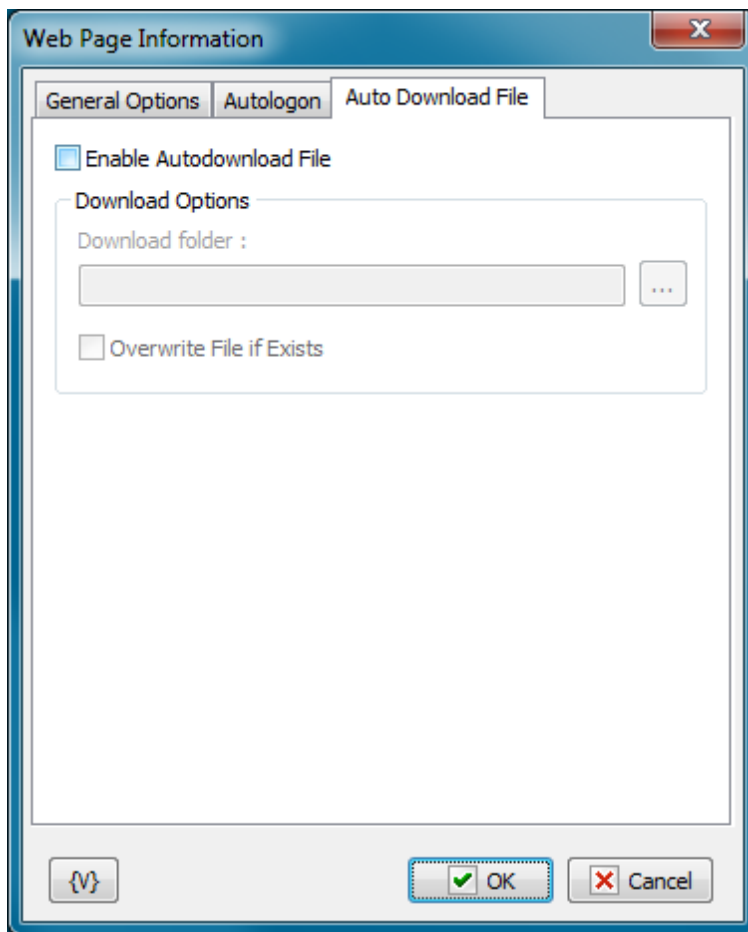

User name

A name of a user for authorization. Variables can be used.

Password

A password for authorization. Variables can be used.

Auto Download file

Enable Auto-download File

It switches on the mode of automatic file downloading. If auto-download is off, downloading occurs in a usual mode requesting a folder and a file name.

Download Folder

Specify the folder in which the file will be downloaded automatically. It will be downloaded with the file name by default.

Overwrite File If Exists.

Switch on this checkbox if you want the action to overwrite a file, on condition there is a file with the same name in this folder. Otherwise the downloaded file will be renamed.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

4.24 Regular Expressions

This plugin is for experts and connoisseurs of regular expressions. Regular expressions are very powerful mechanism for searching and replacing expressions in a text.

We give neither description nor syntax of regular expressions here because they would occupy a lot of space. Many books are devoted to regular expressions. Our description of them would virtually copy other sources.

If you read the book ***Mastering Regular Expressions*** by **Jeffrey E.F. Friedl** you will know everything about regular expressions (or almost everything). For quick study visit the site <http://www.regular-expressions.info/> . The site is completely devoted to regular expressions and different dialects. You can also find short manuals on syntax of regular expressions there. For example:

<http://www.regular-expressions.info/reference.html>

<http://www.regular-expressions.info/refadv.html>

<http://www.regular-expressions.info/refreplace.html>

You can find links to other editions on regular expressions here:

<http://www.regular-expressions.info/books.html>

In a few words, by means of regular expressions you can seek a phrase (an expression) in a text using an expression mask. You write a mask of an expression you seek and then the engine of regular expressions will find real phrases in a text which corresponds to the mask. Search of a substring (or of a symbol combination) in a text is the simplest example of using regular expressions.

4.24.1 RegExp Loop

Using RedExp Loop you can find all entries of a phrase you seek in a text and process them in a loop. A phrase mask is specified by a regular expression. The search result of every iteration is saved in a variable as a standard comma-separated string. The whole sought-for phrase is always a zero element. The following elements contain sub-expressions if they are present in a regular expression. Sub-expressions are a part of phrase which is put into parentheses. A sub-expression number is the ordinal number of an opening parenthesis if you read the expression from the left to the right.

For example, the regular expression for search of links addresses in HTML text is:

```
<a\s+href\s*=\s*"([\s])*">\s*(<[^\>]*>?)\s*</a>
```

This regular express contains two sub-expressions:

- The link address
- The link description

You can put the modifier which is not a sub-expression in the beginning of expression: (?i).

This combination means the search has to be done with no account taken to the register. The symbol ? in modifier always follows an opening parenthesis but goes before a closing one.

For example: (?im). Modifiers can be in any place of a regular expression. See below the description of search modes and corresponding modifiers.

General

External Text

Input the name of the text file in which the search will be implemented. Variables can be used.

Specified Text

In this field specify the text in explicit form on which you want to search. You can use variables.

Pattern (Regular Expression)

Input a regular expression (a phrase mask) for the search in a text. You can find description of regular expression syntax and manuals on the site <http://www.regular-expressions.info/>

Save Found Expression to Variable

Input the name of a variable in which you want to save the search result. If the search-for phrase is found, the search result will be saved in the variable like a standard comma-separated string. To extract a separate element you need to refer to the variable as an array.

For example:

```
{MyVar(0)}
```

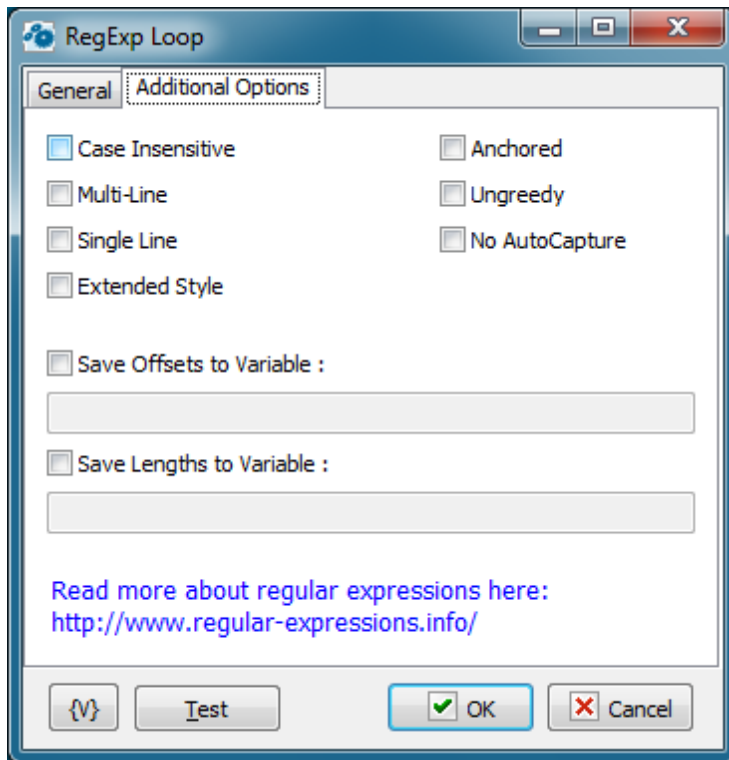

```
{MyVar(1)}
```

Etc.

The zero element of array is always the search-for phrase as a whole.

The next array elements are sub-expressions in the search-for phrase which are highlighted in the regular expression by parenthesis (certainly, if there are such). If you didn't specify any sub-expressions in the regular expression, the resultant array would consist of a single element, which is zero element.

Additional options

Case Insensitive

Tries to match the regex without paying attention to case. If set, 'Bye' will match 'Bye', 'bye', 'BYE' and even 'byE', 'bYe', etc. Otherwise, only 'Bye' will be matched. Equivalent to (?i) modifier. The modifier (?-i) switches off the mode case insensitive.

MultiLine

The ^ (beginning of string) and \$ (ending of string) regex operators will also match right after and right before a newline in the Subject string. This effectively treats one string with multiple lines as multiple strings. Equivalent to Perl's (?m) modifier. The modifier (?-m) switches off the mode multiline.

Single Line

Normally, dot (.) matches anything but a newline (\n). With Single Line mode, dot (.) will match anything, including newlines. This allows a multiline string to be regarded as a single entity. Equivalent to Perl's (?s) modifier. The modifier (?-s) switches off the mode single line.

Note that MultiLine and Single Line can be used together.

Extended Style

Allow regex to contain extra whitespace, newlines and Perl-style comments, all of which will be filtered out. This is sometimes called "free-spacing mode".

Anchored

Allows the regex to match only at the start of the subject or right after the previous match.

Ungreedy

Repeat operators (+, *, ?) are not greedy by default (i.e. they try to match the minimum number of characters instead of the maximum).

No Autocapture

Is a non-capturing group, only named groups will be captured.

Save Offsets to Variables

If you want to determine positions of found expressions from the beginning of a text switch on this flag and input a variable name, the positions will be saved as a comma-separated string. A zero element - this is a position of a whole expression. The next elements are positions of subexpressions. The beginning of a text corresponds to the position 1.

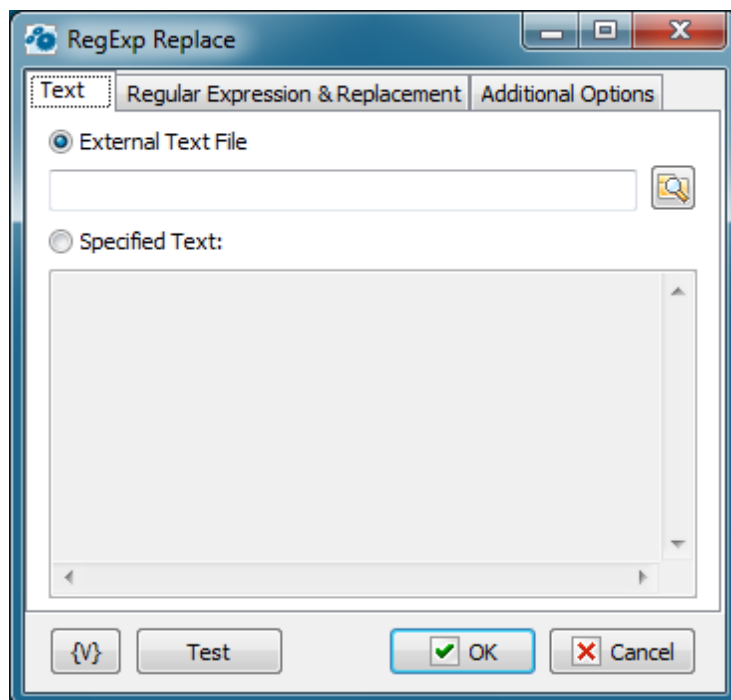

Save Lengths to Variables

If you want to determine the lengths of found expressions (by symbols), switch on this flag and input the variable name. The lengths will be saved as a comma-separated string. A zero element is a length of a whole expression. The next elements are lengths of subexpressions.

4.24.2 RegExp Replace

This action performs search and replacement of regular expressions in a text. You can both replace the found expression entirely and combine a new one from the found subexpressions.

Text

External Text

Input the name of the text file in which the search will be implemented. Variables can be used.

Specified Text

In this field specify the text in explicit form on which you want to search. You can use variables.

Regular Expression & Replacement

Pattern (Regular Expression)

Input a regular expression (a phrase mask) for the search in a text. You can find description of regular expression syntax and manuals on the site <http://www.regular-expressions.info/>

Replacement

Input a text for replacement of the found expression. Variables and the found subexpressions can be used in the expression.

\$0 corresponds to the whole found expression.

\$1-\$9 are subexpressions from 1 to 9, one after another.

For example:

*If you want to put found expression into quotes write the following replacement:
"\$0"*

Replace Mode

- *All entries* - all matched entries will be replaced
- *First entry* - the action make replacement only at first entry
- *Last Entry* - the action make replacement only at last entry

Save Result to Variable

Input a variable name in which you want to put a text after performed replacements.

Additional options

Case Insensitive

Tries to match the regex without paying attention to case. If set, 'Bye' will match 'Bye', 'bye', 'BYE' and even 'byE', 'bYe', etc. Otherwise, only 'Bye' will be matched. Equivalent to (?i) modifier. The modifier (?-i) switches off the mode case insensitive.

MultiLine

The ^ (beginning of string) and \$ (ending of string) regex operators will also match right after and right before a newline in the Subject string. This effectively treats one string with multiple lines as multiple strings. Equivalent to Perl's (?m) modifier. The modifier (?-m) switches off the mode multiline.

Single Line

Normally, dot (.) matches anything but a newline (\n). With Single Line mode, dot (.) will match anything, including newlines. This allows a multiline string to be regarded as a single entity. Equivalent to Perl's (?s) modifier. The modifier (?-s) switches off the mode single line.

Note that MultiLine and Single Line can be used together.

Extended Style

Allow regex to contain extra whitespace, newlines and Perl-style comments, all of which will be filtered out. This is sometimes called "free-spacing mode".

Anchored

Allows the regex to match only at the start of the subject or right after the previous match.

Ungreedy

Repeat operators (+, *, ?) are not greedy by default (i.e. they try to match the minimum number of characters instead of the maximum).

No Autocapture

Is a non-capturing group, only named groups will be captured.

Save the number of Replacements to Variable

If you need to save the number of performed replacements, switch on this checkbox and then input the variable name.

4.24.3 RegExp Match

This action is in fact a simplified version of RegExp Loop. By means of this action it is possible to determine if a string (or a text) corresponds to the specified regular expression and also to extract the first or the last entry.

General

External Text

Input the name of the text file in which the search will be implemented. Variables can be used.

Specified Text

In this field specify the text in explicit form on which you want to search. You can use variables.

Pattern (Regular Expression)

Input a regular expression (a phrase mask) for the search in a text. You can find description of regular expression syntax and manuals on the site <http://www.regular-expressions.info/>

Save TRUE or FALSE to variable

Input the variable name in which you want to save the check result.

Additional options

Case Insensitive

Tries to match the regex without paying attention to case. If set, 'Bye' will match 'Bye', 'bye', 'BYE' and even 'byE', 'bYe', etc. Otherwise, only 'Bye' will be matched. Equivalent to (?i) modifier. The modifier (?-i) switches off the mode case insensitive.

MultiLine

The ^ (beginning of string) and \$ (ending of string) regex operators will also match right after and right before a newline in the Subject string. This effectively treats one string with multiple lines as multiple strings. Equivalent to Perl's (?m) modifier. The modifier (?-m) switches off the mode multiline.

Single Line

Normally, dot (.) matches anything but a newline (\n). With Single Line mode, dot (.) will match anything, including newlines. This allows a multiline string to be regarded as a single entity. Equivalent to Perl's (?s) modifier. The modifier (?-s) switches off the mode single line.

Note that MultiLine and Single Line can be used together.

Extended Style

Allow regex to contain extra whitespace, newlines and Perl-style comments, all of which will be filtered out. This is sometimes called "free-spacing mode".

Anchored

Allows the regex to match only at the start of the subject or right after the previous match.

Ungreedy

Repeat operators (+, *, ?) are not greedy by default (i.e. they try to match the minimum number of characters instead of the maximum).

No Autocapture

Is a non-capturing group, only named groups will be captured.

Save Found Subexpressions

If you need to save a found expression in a variable, switch on this checkbox and then fill in the saving parameters. You can save either the first entry or the last one. The found expression with its subexpressions will be saved as a comma-separated string. A zero element is the whole expression. The next elements are subexpressions in order.

4.24.4 RegExp COM object

RegExp COM object is designed for using in Basic script.

Object name: RegExpCOM.RegexpClass

Object GUID: ['{0762F9AA-BD80-4BFC-B469-854866F114CC}']

Example of using

Below is an example of using RegExp COM object in Basic script

```
Sub Main

Dim obj As Object
Dim i As Long
Dim cnt As Long
Dim res As Boolean
Dim s As String

Set obj = CreateObject( "RegExpCOM.RegexpClass" )

obj.Subject = RoboTaskApp.ExpandText("{txt}")
obj.RegExp = RoboTaskApp.ExpandText("{regex}")

res = obj.Match
While res
  cnt = obj.SubExpressionCount
  s = ""
  For i = 0 To cnt
    s = s + obj.SubExpression( i ) + Chr(10)
  Next i
  MsgBox( s )
  res = obj.MatchAgain
Wend

End Sub
```

Also you can make permanent link to RegExpCOM Library in the script. In this case you should declare the object so:

```
Dim obj As RegExpClass
```

And create the object by using New directive

```
Set obj = New RegExpClass
```

Members of object

Anchored

Read-Write property, type – Boolean

Get or set anchored mode of object.

Caseless

Read-Write property, type – Boolean

Get or set case insensitive mode of object.

Extended

Read-Write property, type – Boolean

Get or set extended mode of object.

Match

Read-only property, type – Boolean

Find first match. Returns TRUE if expression was found.

MatchAgain

Read-only property, type – Boolean

Find next match. Returns TRUE if expression was found.

Multiline

Read-Write property, type – Boolean

Get or set multiline mode of object.

NoAutoCapture

Read-Write property, type – Boolean

Get or set NoAutoCapture mode

RegExp

Read-Write property, type – String

Get or set regular expression.

Replace

Read-only property, type - String

It replaced found expression by "replacement" and returns new expression.

This property can be used only after successful *Match* or *MatchAgain*.

ReplaceAll

Read-only property, type - Long

Replace all matches. Returns the number of replacements.

Replacement

Read-Write property, type - String

The replacement string. Used in *Replace* and *ReplaceAll*.

SingleLine

Read-Write property, type - Boolean

Get or set single line mode of object.

SubExpression(ByVal idx as Long)

Read-only property, type- String

Returns sub-expression by index.

This property can be used only after successful *Match* or *MatchAgain*.

SubExpressionCount

Read-only property, type- Long

Returns the number of sub-expressions.

This property can be used only after successful *Match* or *MatchAgain*.

SubExpressionLength(ByVal idx as Long)

Read-only property, type - Long

Returns the length of sub-expression by index.

This property can be used only after successful *Match* or *MatchAgain*.

SubExpressionOffset(ByVal idx as Long)

Read-only property, type - Long

Returns the offset (position) of sub-expression by index.

This property can be used only after successful *Match* or *MatchAgain*.

Subject

Read-Write property, type – String

Get or set the text to process.

Ungreedy

Read-Write property, type – Boolean

Get or set un-greedy mode of object.

4.25 Screenshot

This plug-in unites actions of taking a screenshots, snapshots of necessary window or color of pixel on the screen or in the window.

4.25.1 Window Snapshot

This action allows to take a snapshot of a window and save the window image into a file.

Window parameters.

This action allows to use three modes of window selection to take a snapshot:

- **Use Window Parameters** – search of a window according to parameters (Window Caption, Window class);
- **Use Windows Handle** – according to the Handle of the window. Each window in a system has its unique Handle. It can be got in the loop Window Loop. For example, the following task can be done: to take all snapshots of windows which have the word Notepad in their captions.
- **Use Current window** – to use the current active window.

When using the mode Use Window Parameters, the parameters of the window for a search are available to the user.

Window Caption

Switch on this checkbox if you want to use the Window Caption to search a window. Then fill in the field for the search of the Window Caption. The field can be filled in automatically when you select the window from the window list. You need to click the button to the right of the entry field. The usage of variables is allowed.

Window caption must match exactly

If you want a Window Caption to be exactly matched to the input string, switch on this checkbox.

Window Class

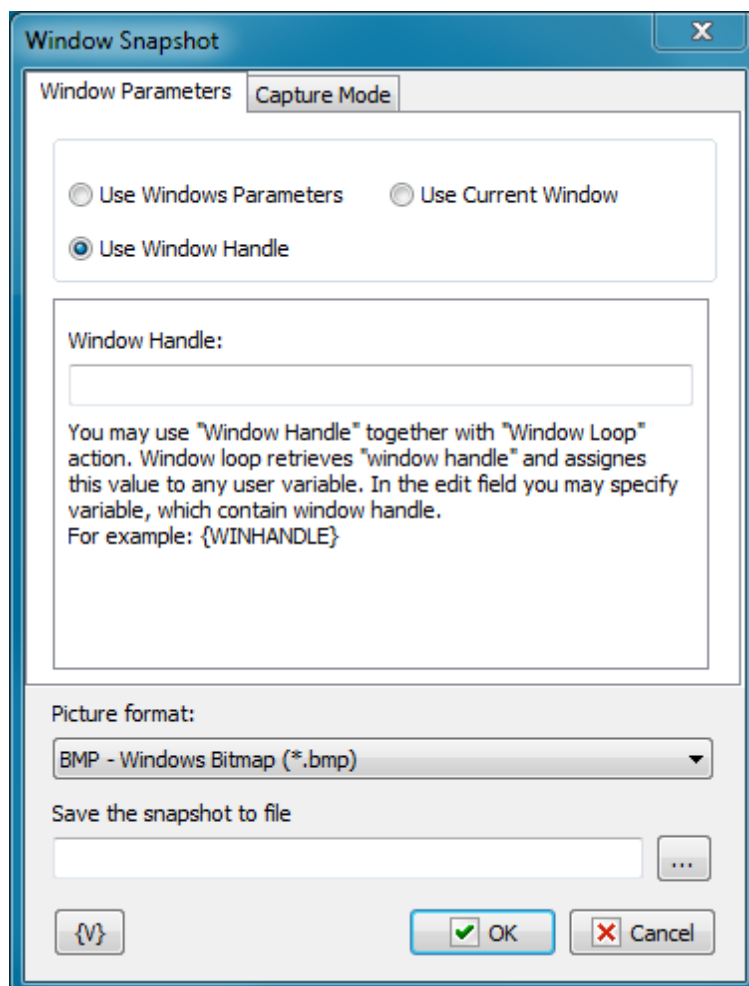

Switch on this checkbox if you want to use the Window Class for a search of a window. Then, fill in the field for the search of the Window Class. The field can be filled in automatically when you select the window from the window list. You need to click the button to the right of the entry field. The usage of variables is allowed.

Window class must match exactly

If you want a Window Class to be exactly matched to the input string, switch on this checkbox.

Select Window on the screen

Using this button you can select any window in a screen and fill in fields automatically. Just direct the mouse cursor onto the necessary window and click Ctrl to select the window or the Esc to cancel the operation. When moving the mouse cursor, the current window is highlighted in a red frame. You can use the mouse to manipulate with windows.

Window Handle

When using of the mode Use Window Handle, this parameter is available to the user. The Window Handle identifies the window explicitly. It is convenient to use this mode in the Window Loop. The loop allows to perform the selection of windows according to necessary criteria and save the window handle into a variable. By means of the window handle it is possible to take a snapshot

Capture mode

The action allows to take snapshot of the whole window or of a part of him.

Full Window.

Select this point if you want to take the screenshot of the whole window.

Window Region.

If you want to take the screenshot only of a part of a window, select this point and input the position data of a rectangular region of the window: **Left**, **Top**, **Height**, **Width**. You can also

specify the rectangular region on a screenshot interactive clicking the button Select Region on Window Snapshot.

Picture Format

Snapshot of a window is a graphic image. It can be saved in the different formats:

- **BMP** – standard Windows bitmap;
- **Jpeg** – Joint Photographic Experts Group format;
- **PNG** – portable network graphics format
- **GIF** – Graphics Interchange Format

Save the snapshot to file

Specify the file name into which the snapshot need to be saved.

4.25.2 Window Pixel

This action allows to get the color of a window pixel according to the specified coordinates and save it into a variable. The color of a pixel is a number. It can be compared with a sample like an ordinary number or with another color using a tolerance.

Window Selection Mode

The action allows to use three selection modes of a window to take a screenshot:

- **Use Window Parameters** – the search of a window according parameters (Window Caption, Window class);
- **Use Window Handle** – according the Window Handle. Each window in a system has the unique Handle. It can be got in the loop Window Loop. For example, the following task can be made: to take all screenshots, which have the word Notepad in their captions.
- **Use Current window** – use the current active window.

Window Caption

Switch on this checkbox if you want to use the Window Caption for a search of a window. Then, fill in the field for the search of the Window Caption. The field can be filled in automatically when you select the window from the window list. You need to click the button to the right of the entry field. The usage of variables is allowed.

Window caption must match exactly

If it is necessary the Window Caption to be match exactly with the entry string, switch on this checkbox.

Window Class

Switch on this checkbox if you want to use the Window Class for a search of a window. Then, fill in the field for the search of the Window Class. The field can be filled in automatically when you select the window from the window list. You need to click the button to the right of the entry field. The usage of variables is allowed.

Window class must match exactly

If it is necessary the Window Class to be match exactly with the entry string, switch on this checkbox.

Select Window on the screen

Using this button you can select any window in a screen and fill in fields automatically. Just direct the mouse cursor on the necessary window and click Ctrl to select the window or Esc to cancel the operation. When moving the mouse cursor, the active window is highlighted in a red frame. You can use the mouse to manipulate with windows.

Window Handle

When using of the mode Use Window Handle, this parameter is available to the user. The Window Handle identifies the window explicitly. It is convenient to use this mode in the Window Loop. The loop allows to perform the selection of windows according to necessary criteria and save the window handle into a variable. By means of the window handle it is possible to take a snapshot

Coordinates

Specify the coordinates of a pixel from the top left corner of a window snapshot. The usage of variables in the expression is allowed. You can specify the coordinates interactive clicking the

button Select Point.

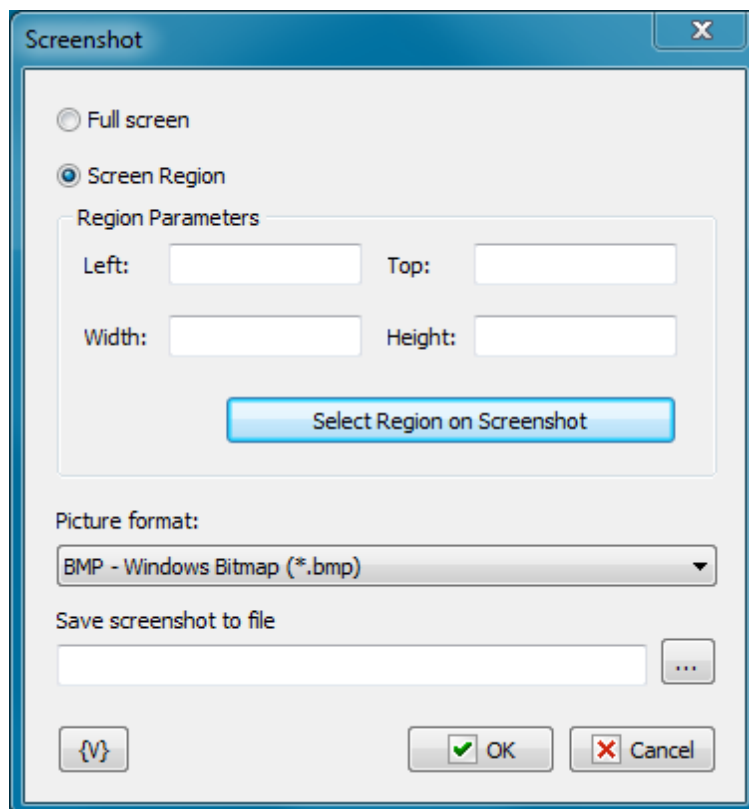

Save Color To Variable

Specify the name of the variable in which it is necessary to save the color. The color of a pixel is a number. For the convenience of sensing, the action saves color in a hexadecimal look.

For example, \$FFFF00, \$800000

4.25.3 Screenshot

The action allows to take a snapshot of the whole screen (or of a part of it) and save it into a file.

Full screen

Select this option if you need to take the snapshot of a whole screen.

Screen region

Select this option if it is necessary to save the snapshot of a rectangular region of the screen.

Determine the coordinates of the region: **Left, Top, Height, Width.**

You can determine the coordinates of a rectangular region interactive clicking the button "Select Region on Screenshot".

Picture Format

Screenshot is a graphic image. It can be saved in the different formats:

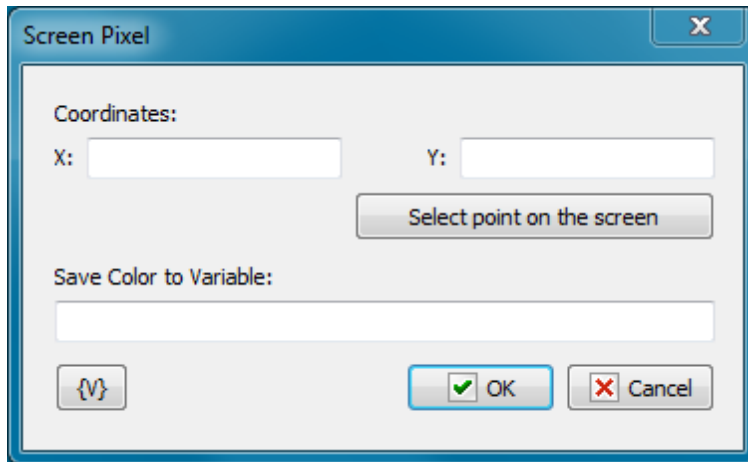

- **BMP** – standard Windows bitmap;
- **Jpeg** – Joint Photographic Experts Group format;
- **PNG** – portable network graphics format
- **GIF** – Graphics Interchange Format

Save screenshot to file

Specify the file name into which the snapshot need to be saved.

4.25.4 Screen Pixel

This action allows to get the color of a window pixel according to the specified coordinates and save it into a variable. The color of a pixel is a number. It can be compared with a sample like an ordinary number or with another color using a tolerance.

Coordinates

Specify the coordinates of a pixel. The usage of variables is allowed. You can specify the coordinates interactive in the picture clicking the button "Select Point on the screen".

Save Color to Variable

Specify the name of the variable in which it is necessary to save the color. The color of a pixel is a number. For the convenience of sensing, the action saves color in a hexadecimal look.

For example, \$FF80E0, \$808080

4.25.5 Color Compliance

This action allows to compare a color with the standard sample color. To identify color compliance it can be specified some tolerance. 0 means exact compliance. The maximum value of a tolerance is 255. The maximum value of a tolerance means that the result of the compliance check of any two color always is TRUE.

The compare result can be saved into a variable for the next processing in following steps of the task.

1-st color, 2-nd color

Specify two colors for comparing. You can specify the color as an ordinary number or in a hexadecimal look (beginning from the symbol \$). The color can be selected from a palette or from any point of a screen clicking the button to the right of the edit field. The usage of variables is allowed.

Tolerance

Specify the necessary tolerance to compare two colors. On default, it is 16. 0 corresponds to the exactly coincidence.

255 is the maximum value. When a value is maximum the result of comparing of any two colors is TRUE.

Save TRUE or FALSE to variable

Input the name of the variable in which it is necessary to save the result of the comparing.

4.25.6 Wait for Pixels

The action waits for the change of pixels color on a screen or in an appointed window. This is a standard way to identify finishing some operation in a system: a picture or an inscription will change. Or some area of a window (or screen) will change its color.

The action pauses the executing of a task and waits for changing of pixels color on a screen or in a selected window. The action will continue to implement the task when the condition of correspondence of colors of the selected pixels is fulfilled.

You can specify a set of pixels (one or several) in this action. It is necessary to specify the required color and the tolerance of color comparing for each pixel.

You can specify the condition of color coincidence for a set of pixels:

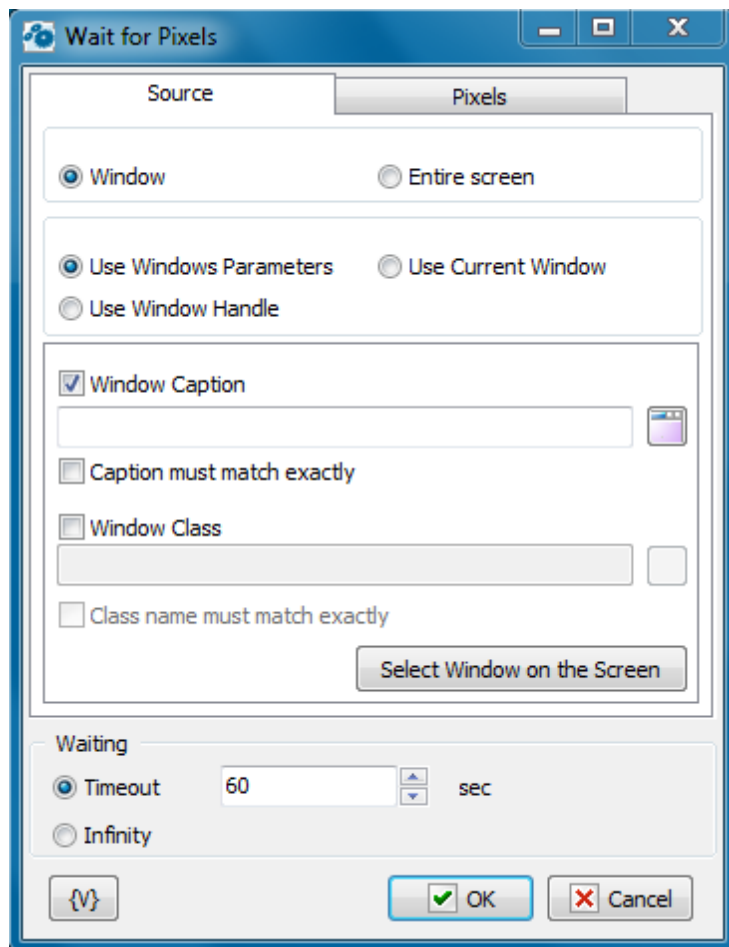

- Match ALL of the following pixels (AND)
- Match ANY of the following pixels (OR)

Thereby, you can specify the exact enough condition of changes on a screen.

If the action has not waited for implementation of the condition for a predetermined time, the action generates the error "*Timeout error*".

If the required window has not been found to the moment of a start of a task, the action generates the error "*Window is not found*".

Source tab

When you determine parameters of an action, at first you need to specify the source of a picture:

- **Window** - This is a separate window. All coordinates of pixels will be determined concerning the upper left corner of this window. If you have selected the window as a source, you need to specify the window parameters.
- **Entire screen** - This is a screen with all visible windows.

The window parameters are similar to the parameters in the actions [Window Snapshot](#)^[292], [Window Command](#)^[204], [Window Size and Position](#)^[209], [Window Elements loop](#)^[210].

Window Parameters Mode

- **Use Window parameters** - Use the Window Caption and the Window Class to look for the necessary window.
- **Use Window Handle** - This is a search for a window by a handle. The handle can be got in the loop Window Loop, from the trigger Wait for Window or some other way.
- **Use current window** - This is a current window in a moment of the executing of the action. This mode does not require any additional parameters.

Use Window parameters Window Caption.

If you want to search for a window by means of its caption, switch on this checkbox and input the expected window caption. You can input only part of the caption. In this case the action will check availability of the input part in the window caption.

Caption Must Match Exactly

If you need the exact coincidence of a window caption, switch on this checkbox.

Window Class.

If you want to search the window by a window class, switch on this checkbox and input the expected name of the window class. You can input only part of the name. In this case the action will check availability of the input line in the name of the window class.

Class Name Must Match Exactly.

If you need the exact coincidence of a window class, switch on this checkbox. Usually it is worthwhile to search by the whole class name, because a window class is permanent and does not change its value during the "life" of the window, unlike a caption.

Select Window on the Screen.

When pressing this button, you turn on the mechanism of selection a window on the screen. The window, which the mouse pointer points on, highlights with a red frame. Meanwhile, you can use the mouse to perform some actions. To select the necessary window, press *Ctrl*. To cancel - press *Esc*. When selecting a window, the fields Window Caption and Window Class are filled in automatically.

Window Handle.

Input the expression containing a window handle. This parameter is used for the mode Use Window Handle. A window handle is just a number, identifier of a window in a current session of system work.

Pixels tab

You need to specify the pixel set for checking on this tab.

List of pixels

You can edit a list using the buttons *Add*, *Edit* and *Remove*.

By means of an edit window you can change pixel parameters both manually and by means of interactive instruments.

Pixel parameters:

X, Y - It is coordinates of a pixel from the left corner. If a source of a picture is a window, coordinates are determined from the upper left corner of the screen window.

Pattern color - This is a pattern of the color with which the action will compare the color of a pixel. Color is just a number. For comfort it is written in hexadecimal.

For example, \$0066FF00 or \$66FF00.

In hexadecimal you can write color using 6 symbols (as RGB): the first couple (younger) is red, the second couple is green, the third couple (elder) is blue color.

Tolerance - This is an accuracy of color coincidence. The error can be changed from 0 to 255 (in hex from 00 to FF). When it is 0, it is exact color coincidence. When it is 255, it is a coincidence with any color.

Tolerance is an acceptable difference between two colors for any component RGB (Red - Green - Blue). Every component of the color can be changed from 0 to 255 (from 00 to FF in

hexadecimal).

On default, the tolerance is 16.

Waiting

There are two options:

- **Timeout** - It is waiting time in seconds. On default, it is 60 seconds. If the action has not found out the implementation of the condition within the timeout period, the action generates the error "*Timeout error*".
- **Infinity** - This is not limited waiting time. Pay attention, if you specify an illegal condition of the checking of pixels, the task can "hang down" and it can be finished by means of the function "Kill task" only.

4.26 XML Documents

By means of these actions can be created an XML document or analyze a ready one. XML document is a text file written according to the syntax XML. Generally speaking, XML file can be created or opened with any text editor. But sometimes it is laboriously enough to follow all features of the XML syntax in a manual mode.

4.26.1 XML Create Node

XML node is a fundamental element of XML document. Every XML node can contain some value or a set of nested XML nodes. Also every node can have arbitrary number of attributes. Roughly speaking, XML document is an XML node which contains inserted nodes with information or with another inserted nodes.

That is, an XML document can contain any structured information.

The image shows a dialog box titled "XML Create Node". It has a close button (X) in the top right corner. The dialog is divided into several sections:

- Name:** A text input field containing the word "Library".
- Text:** A large, empty text area with vertical scrollbars.
- Attributes:** A table with two columns: "Name" and "Value".

Name	Value
version	1.0
description	My books
- Below the attributes table are three buttons: "+ Add", "Edit" (with a pencil icon), and "X Delete".
- Save XML to Variable:** A text input field containing the word "root".
- At the bottom left is a button with a curly brace icon "{ }".
- At the bottom right are two buttons: "OK" (with a green checkmark icon) and "Cancel" (with a red X icon).

Name

The name of a node. This is an identifier of the node. It can contain Latin symbols and numbers without any whitespace or another delimiters.

Text

This is a value of a node. Every node can contain either some value or inserted nodes.

Attributes

Attributes of a node. Every identifier has the name and the value. The composition of attributes depends on purpose of a documents and defined tasks. The order of attributes does no matter. A node can be without any attributes.

Save XML to Variable

Enter the name of a variable into which created node will be saved. The node will be saved as a text in the XML format.

4.26.2 XML Add Childnode

The action allows adding a child node to another node.

Parent Node (XMLText)

Specify a parent node. The node can be specified as an XML text explicitly. For example:

```
<books description="My books">
  <book>
    <author>George Orwell</author>
    <name>1984</name>
  </book>
  <book>
    <author>George Orwell</author>
    <name>Animal Farm</name>
  </book>
</books>
```

Also the node can be specified by means of the variable in which the node is written down. For example:

```
{record}
```

Child node (XML text)

Specify the child node which is necessary to add into parent node. The node can be also specified as a XML text or by means of variables.

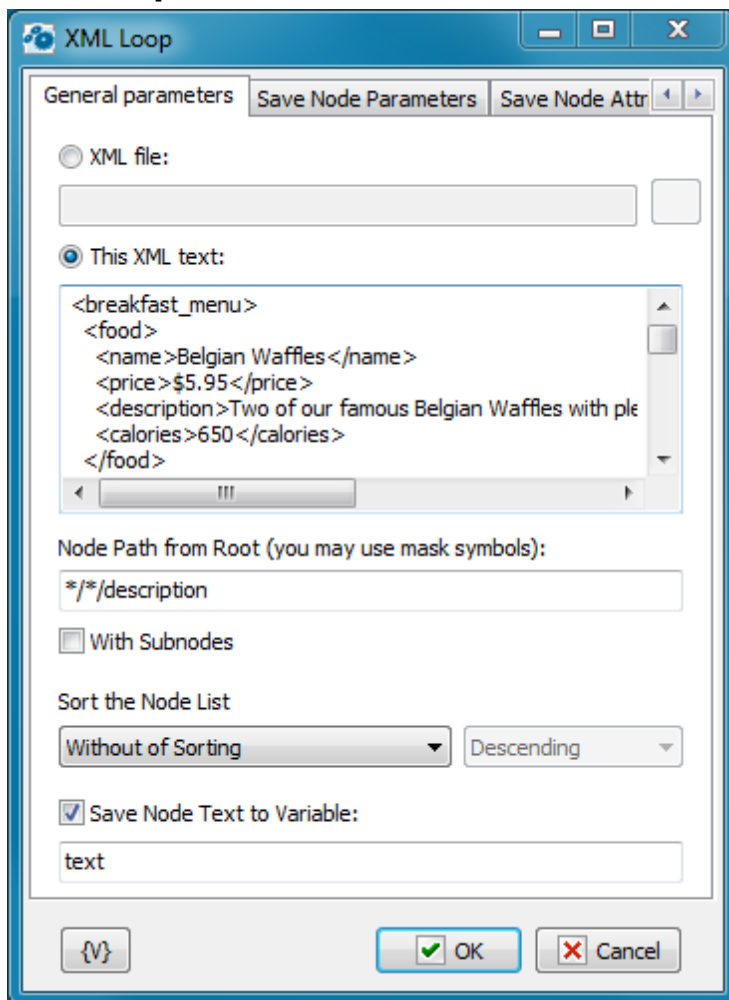

Save XML to Variable

Specify the variable into which the result is necessary to save. The result is saved as a text in XML format.

4.26.3 XML Loop

The XML Loop allows to get the information about nodes of the document in a loop. When of every cycle iteration it is possible to save various parameters of the node and the node itself into variables. By means of the XML Loop it is possible to analyze or to process the information enclosed in XML.

General parameters

XML File

Read XML from file. This option is recommended if XML contain encoded strings. When the action reads it from file it decodes all encoded strings automatically.

The most popular *UTF-8* encoding. XML file should have corresponding header. For example:

```
<?xml version="1.0" encoding="utf-8"?>
```

XML

Specify the XML text which you want to analyze. The text can be specified explicitly or with using of variables.

Node Path from Root

The Node Path is a criterion of selecting of loops from an XML document.

Specify a path of nodes from/of a root that you want to enumerate. It is possible to use mask symbols:

- ? - means any single symbol.
- * - means arbitrary number of symbols.

Instances of usage:

```
*\*\description  
breakfast_menu\*\description  
breakfast_menu\food\description  
breakfast_menu\food\*
```

If you want to enumerate all nodes beginning from a root, specify just the symbol "*" with switched parameter *With Subnodes*.

With Subfolders

If you want to enumerate all nodes including nested nodes, switch on this checkbox.

Save Node Text to variable

If you need to save a node text, switch on this checkbox and enter the variable name.

Save node parameters

The rest of node parameters are collected in this group of parameters.

Save XML Node to Variable

To save the whole node, switch on this checkbox and enter the variable name.

Save Node Name to Variable

To save the node name, switch on this checkbox and enter the variable name.

The fact of the matter is that sometimes you cannot know a node name beforehand. For example, this is possible when you select nodes according a mask:

```
breakfast_menu\food\*
```

Save Node Path to Variable

To save the path of a node, switch on this checkbox and enter the variable name.

Save Node Depth to Variable

To save the depth of enclosure of the node, switch on this checkbox and enter the variable name. A node depth is a number, 0 corresponds to a root element.

Save Child Count to Variable

To save quantity of child nodes, switch on this checkbox and enter the variable name.

Save Node Attributes

On this tab one can specify the attributes which values are necessary to be saved into variables. It is necessary to specify parameters for every attribute:

- **Name** - The attribute name
- **Variable** - The name of the variable in which it is necessary to save the attribute value.
- **Default value** - The value which is written into a variable if the attribute is absent.

4.26.4 XML Save

The action saves an XML text into a file. In some cases it possible to use the action Write Text File. But it is better to use the XML Save because this action automatically corrects the text format when saves it:

- Adds a header of XML
- Automatically converts non-ASCII symbols into the UTF8 format.

The action always saves the text as a common ASCII text with necessary conversions. Such conversions are not need to save in the memory because the XML document is always saved in the memory in the *Unicode* mode.

XML

Specify the text of the XML document which you want to save. The text can be specified explicitly or with using of variables.

File Name

Specify the name of the file into which is necessary to save the XML document.

If File Exists

The action if the specified file exists already:

- **Rename** - The file will be saved under a different name
- **Overwrite** - The file will be overwritten.
- **Raise an Error** - The action generates the error File Already Exists.

4.27 Script tools

This plug-in uses a system script engine and allows to apply program inserts directly in a task. Scripts can be written in JavaScript (JS) or VB Script (VBS)

Syntax of JavaScript language is described in Microsoft documentation: [http://msdn.microsoft.com/en-us/library/hbxc2t98\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/hbxc2t98(v=vs.84).aspx)

Syntax of VB Script language is described in Microsoft documentation: [http://msdn.microsoft.com/en-us/library/t0aew7h6\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/t0aew7h6(v=vs.84).aspx)

4.27.1 Script extensions

The *RoboTask* gives some extensions of the language: several additional functions. You can use these functions freely in your texts of scripts. Notice that the JavaScript is case sensitive. But the functions of extensions work insensitive to a using register. Thereby, the expressions

```
LogMessage("Hello World!!!");  
logmessage("Hello World!!!");
```

are identical.

function LogMessage(AMessage)

The function outputs a message to a log. In edit mode of a script, the function outputs a message to the log of the editor. When a task works, a message is output to a log of the task in the mode *User Message*.

AMessage - the string to output

function include(ScriptFileName)

This function returns the text of specified script file.

ScriptFileName - The name of file which is necessary to load.

You can execute this text in your script. Just put these into your script:

for [VB Script](#)^[319] action use

```
execute include("d:\myscripts\script.txt")
```

For [JS Script](#)^[314] action use

```
eval(include("d:\\myscripts\\script.txt"));
```

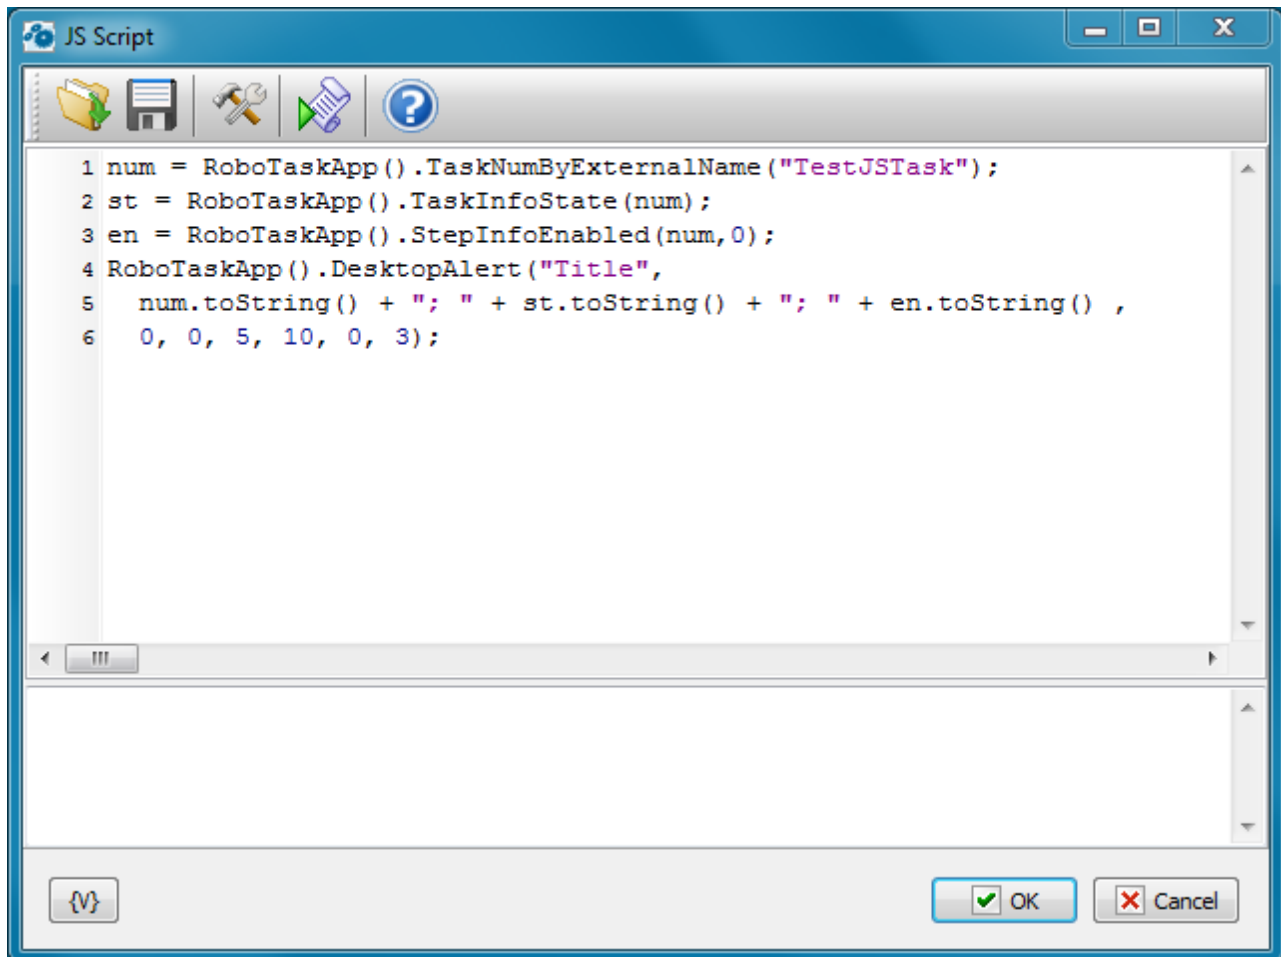

function RoboTaskApp()

This function returns the COM object *RoboTask*. This object allows to use some functions of the *RoboTask* directly from a script. The description of the object is in the chapter ["RoboTaskApp Object"](#)^[361].

4.27.2 JS script

This action allows to perform a program, which is written in JavaScript. Notice that the languages Java and JavaScript are not the same, although they are very alike. The documentation for the language can be read on the Microsoft site: [http://msdn.microsoft.com/en-us/library/hbxc2t98\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/hbxc2t98(v=vs.84).aspx)

The action editor is a specialized text editor adapted for editing a program code.

Popup proposals.

When pressing the Ctrl-Space, a popup menu with some functions and objects of JavaScript shows up on the screen. One can choose a necessary point from the list and then the editor will insert a proper line/string into a text.

If you began to enter a function name and pressed the Ctrl-Space, only alternatives corresponding to the input line will be left in the popup menu.

Autocomplete.

This function allows to insert standard language constructions into a text automatically. For this you need to enter 2-5 key constructions (identifier of construction) and press the combination Ctrl-J. The editor inserts the whole construction instead of the key word.

The editor supports the next constructions:

Identifier	Description	Insert Statement
if	Simple "if"	<pre> if () { } </pre>
ife	"if .. else"	<pre> if () { } </pre>

	statement	<pre> } else { } </pre>
for	Simple "for" loop	<pre> for (i=0; i< ; i++) { } </pre>
func	Function declaration	<pre> function () { return 0; } </pre>
try	"try .. catch .. finally" block	<pre> try { } catch(e) { } finally { } </pre>
do	"do .. while" loop	<pre> do { } while () </pre>
while	"while" loop	<pre> while () { } </pre>
with	"with" keyword	<pre> with () { } </pre>
swi	"switch" statement	<pre> switch () { case 0: break; case 1: break; default: } </pre>

Interface

Load from file

Load the text of a script from a file.

Save script as file

Save the text of a script into a file.

Additional options

Expand Variables in the script - If to switch on this mode, the RoboTask expands all inserts of variables in a text before running of the script.

Save Final script into variable - If it is necessary to monitor the final text of the script, switch on this checkbox and enter the variable name. This mode is need only for control and

checkout. The fact of the matter is that the substitution of variable values can break down the syntax of a script text. By means of this mode it is possible to get the final script and analyze it if it is necessary.

The field of a log is under the editor. The messages about runtime errors of the script are output into this field. Also the text of messages LogMessage is output here.

Run script

Running of a script from the editor to test. If a runtime error arises, you can see a message about the error in the field of the edit log.

Help

Activation of a help system.

4.27.3 JS Evaluate

This action allows to calculate an expression value and then save it into a variable. The expression has to be written according to the syntax of JS language. The documentation for the language can be read on the Microsoft site: [http://msdn.microsoft.com/en-us/library/hbxc2t98\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/hbxc2t98(v=vs.84).aspx)

The action also allows to connect the function library from an external file or directly in an additional script.

For example, try to calculate the expression

```
sum(5,6) + multi(3,4)
```

And we get the error. The JavaScript language doesn't contain functions sum and multi.

To solve this, it is possible to specify a little library of user functions:

```
function sum(a, b)
{
    return a+b;
}

function multi(a, b)
{
    return a*b;
}
```

In this case the action calculates the result without any troubles. The given example is too simple and is cited for the demonstration solely.

Another example. Calculate the *factorial* of a number. Such function is absent in JavaScript. But it is easy to evade. It takes only to create the simply function:

```
function factorial(a)
{
    if (a>30)
    { //this is synthetic limitation
        throw new Error(1, "Parameter more than 30");
    }
}
```

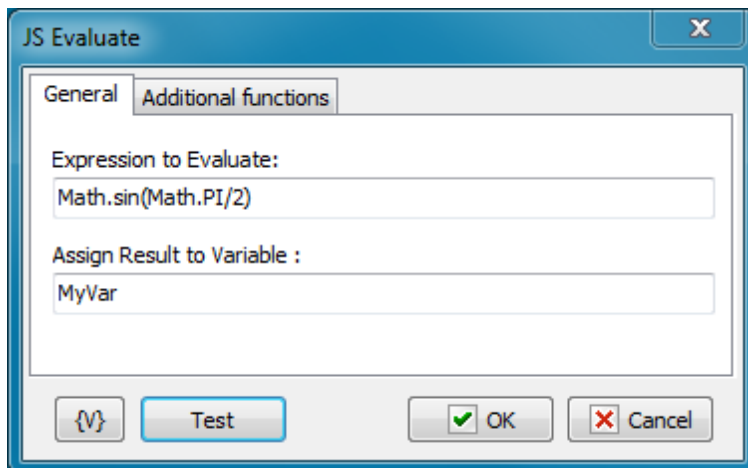

```
    }  
    res = 1;  
    for (i=1; i<=a; i++)  
    {  
        res *= i;  
    }  
    return res;  
}
```

Now we easy can calculate the expression:

```
factorial(15)
```

Given possibility allows to do some specific calculations, that are difficult to be written in one line.

General Tab

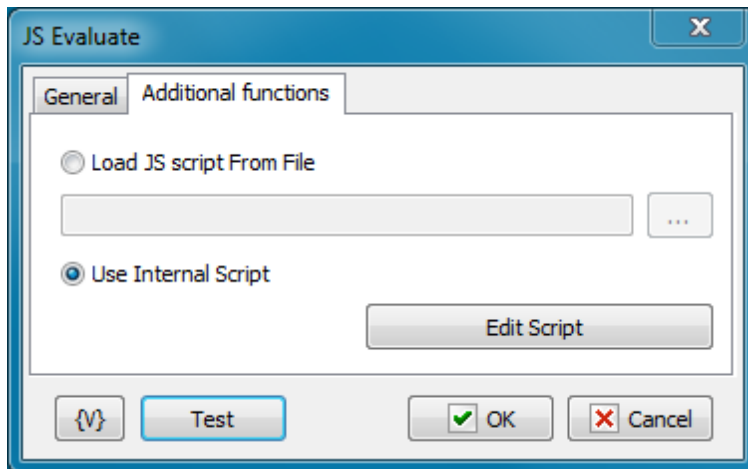

Expression To Evaluate

Write down the expression whose value needs to be calculated. The expression has to be made according to the syntax of JavaScript.

Assign Result to Variable

Enter the name of the variable into which it is necessary to save the result.

Additional Functions

Load JS Script from File

Load the library of additional functions from an external file. Enter a file name or choose it interactively.

The file name can be empty. In this case the action works only with standard functions and objects of JS.

Use Internal Script

If you want to specify functions directly in a task, choose this option. To edit a script, click the button Edit Script. You can see the editor like in the action [JS Script](#)^[314].

The text of a script can be empty. In this case the action works only with standard functions and objects of JS.

4.27.4 VB Script

This action allows to perform a program, which is written in VB Script. Notice that the languages Visual Basic and VB Script are not the same, although they are very alike. The documentation for the language can be read on the Microsoft site: [http://msdn.microsoft.com/en-us/library/t0aew7h6\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/t0aew7h6(v=vs.84).aspx)

The action editor is a specialized text editor adapted for editing a program code.

Popup proposals.

When pressing the Ctrl-Space, a popup menu with some functions and objects of VB Script shows up on the screen. One can choose a necessary point from the list and then the editor will insert a proper line/string into a text.

If you began to enter a function name and pressed the Ctrl-Space, only alternatives corresponding to the input line will be left in the popup menu.

Autocomplete.

This function allows to insert standard language constructions into a text automatically. For this you need to enter 2-5 key constructions (identifier of construction) and press the combination Ctrl-J. The editor inserts the whole construction instead of the key word.

The editor supports the next statements:

Identifier	Description	Insert statement
do	"do" loop	do loop

foreach	"For each" loop	for each in next
for	Simple "for" loop	for i=0 to step 1 next
func	Function declaration template	function () end Function
if	Simple "IF"	if then end if
ife	IF .. Else statement	if then else end if
select	Select case statement	select case case case case end select
sub	Sub procedure declaration	sub () end sub
while	"While" loop	while wend
with	"With" statement	with end with

Interface

Load from file

Load the text of a script from a file.

Save script as file

Save the text of a script into a file.

Additional options

Expand Variables in the script - If to switch on this mode, the RoboTask expands all inserts of variables in a text before running of the script.

Save Final script into variable - If it is necessary to monitor the final text of the script, switch on this checkbox and enter the variable name. This mode is need only for control and checkout. The fact of the matter is that the substitution of variable values can break down the syntax of a script text. By means of this mode it is possible to get the final script and analyze it if it is necessary.

The field of a log is under the editor. The messages about runtime errors of the script are output into this field. Also the text of messages LogMessage is output here.

Run script

Running of a script from the editor to test. If a runtime error arises, you can see a message about the error in the field of the edit log.

4.27.5 VB Evaluate

This action allows to calculate an expression value and then save it into a variable. The expression has to be written according to the syntax of JS language. The documentation for the language can be read on the Microsoft site: [http://msdn.microsoft.com/en-us/library/t0aew7h6\(v=vs.84\).aspx](http://msdn.microsoft.com/en-us/library/t0aew7h6(v=vs.84).aspx)

The action also allows to connect the function library from an external file or directly in an additional script.

For example, try to calculate the expression

```
sum(5,6) + multi(3,4)
```

And we get the error. The VB Script language doesn't contain functions *sum* and *multi*.

To solve this, it is possible to specify a little library of user functions:

```
function sum(a, b)
  sum = a + b
end Function

function multi(a, b)
  multi = a * b
end function
```

In this case the action calculates the result without any troubles. The given example is too simple and is cited for the demonstration solely.

Another example. Calculate the *factorial* of a number. Such function is absent in JavaScript. But it is easy to evade. It takes only to create the simply function:

```
function factorial(a)
  if a > 30 then
    'this is synthetic limitation
    err.raise 1, , "Parameter more than 30"
  end if

  res = 1
  for i = 1 to a
    res = res * i
  next

  factorial = res
end function
```

Now we easy can calculate the expression:

```
factorial(15)
```

Given possibility allows to do some specific calculations, that are difficult to be written in one line.

Expression To Evaluate

Write down the expression whose value needs to be calculated. The expression has to be made according to the syntax of VB Script.

Assign Result to Variable

Enter the name of the variable into which it is necessary to save the result.

Load VB Script from File

Load the library of additional functions from an external file. Enter a file name or choose it interactively.

The file name can be empty. In this case the action works only with standard functions and objects of VB Script.

Use Internal Script

If you want to specify functions directly in a task, choose this option. To edit a script, click the button Edit Script. You can see the editor like in the action [VB Script](#)^[319].

The text of a script can be empty. In this case the action works only with standard functions and objects of VB Script.

4.28 Excel

This group of actions is for working with MS Excel documents. All actions ensure the work by means of application *MS Excel*. Thereby, the MS Office package must have been installed on your computer.

4.28.1 Excel Open Document

This action starts the application MS Excel and opens an existent document or creates a new one. You have to open document first before using other Excel actions.

**Open Existing File**

Open the specified file. If the file does not exist, the action generates a task error.

Create New Empty Document

Create a new file with a specified name. If such file is already exist, the action just opens it.

File Name

Specify the file name. Usage of variables is permitted.

Hide Excel Application

If you need all actions with the document to occur in a hide mode, switch on this checkbox.

4.28.2 Excel Get Cells

This action permits to read the values of table cells and write them into variables of RoboTask. This action demand the document to be opened by means of the [Excel Open Document](#) 

Worksheet

Specify the name or the number of a worksheet of a document. The ordinal number begins from 1.

List of Cells

The list of cells and variables. The coordinates of every cell can be specified with two ways:

- In a style **A1**, that is an address of a column is written with letters but an address of a row is written with numbers. For example: *C3*, *D5*, *BD15*.

The next column after Z is the column *AA*, *AB*, etc.

- In a style **R1C1**. After the letter R is the number of a row beginning from 1, after the letter C is the number of a column beginning from 1.

Each cell corresponds to the variable name in which the action saves the cell value. The variable name can be specified in an explicit form or by using of another variables.

4.28.3 Excel Set Cells

This action permits to change the cell value. This action demand the document to be opened by means of the [Excel Open Document](#)^[324]

Worksheet

Specify the name or the number of a document worksheet. The ordinal number begins from 1.

List of Cells

The list of cells and variables. The coordinates of every cell can be specified with two ways:

- In a style A1, that is an address of a column is written with letters but an address of a row is written with numbers. For example: C3, D5, BD15.
The next column after Z is the column AA, etc.
- In a style R1C1. After the letter R is the number of a row beginning from 1, after the letter C is the number of a column beginning from 1.

Each cell corresponds to the expression which will be written into the cell. The expression is a string which can be written explicitly or by using of variables.

4.28.4 Excel Save Document

This action saves the changed document in the disk. If you need to save the changing in a file, use this action without fail. *The automatic saving does not occurs when a task ends or a document is closed.*

This action does not demand additional settings and saves the file with the name which is specified in the action [Excel Open Document](#)^[324].

4.28.5 Excel Close

This action closes the opened document. The opened document will be closed automatically when a task is executed. As it was said before, the automatic saving does not occur. If you

need to save the changes in the document, use the action [Excel Save Document](#)^[327] before the closing of the document or the ending of the task.

If you want to open two different documents in the task, at the beginning close the first document and then open the second one by means of the [Excel Open Document](#)^[324].

4.29 DataBase

The actions for working with a database are collected in this group. In contrast to actions [SQL Query](#)^[78] и [Dataset Loop](#)^[190], all these actions work in one session. At first you have to open a database ([DB Open](#)^[328]), perform necessary actions and then close the database ([DB Close](#)^[329]). Thereby, you can execute a difficult sequence of actions with a database as a single block.

The actions [SQL Query](#)^[78] and [Dataset Loop](#)^[190] open their session for processing query and serve to perform single queries.

The group of actions DataBase works on basis of the mechanism ADO (ActiveX Data Objects) and can work with any database if the system has a proper driver.

Note: *This feature is available for Business license only*

4.29.1 DB Open

The action opens a database. All actions with a database must begin from opening the database. If you try to process any actions with the database without its opening, you will get the error *Database Is Not Opened*.

Every task permits only one opened database (DB). If you need open another DB, you should close the previous session.

If you try to open the DB when the session is opened, the action will give the warning *Database Connection Is Already Opened* and ignores the operation of opening.

Connection String

Input a connection string to connect to a database. You can use a system constructor pressing the button on the right of the entry field.

Override connection string parameters

If you need to override authorization parameters, turn on this switch and specify the User ID and Password. These parameters will be used while opening the DB.

User ID

Input a new user name.

Password

Input a password.

Note: *This feature is available for Business license only*

4.29.2 DB Close

Closes the currently work session with the database. Any additional parameters are not required.

Note: *This feature is available for Business license only*

4.29.3 DB Exec SQL

Processes an SQL query. The action is similar to the SQL Query action. But this action is performed within an opened database session. Thereby, you can process a series of queries in a single block.

General

SQL Query

Input an SQL query according to syntax. You can use parameters. It is necessary to put the colon (:) in front of the parameter name.

For example:

```
Select * from dept where city = :citypmt
```

citypmt is a parameter of the query.

Assign Rows affected to variable

Turn on this checkbox and input a variable name if you need to save the number of processed records into a variable.

SQL Parameters

Sometimes using of parameters of a query is more convenient instead of generation of the query by means of variables. For example, when the variable value contains quotes or another special symbols. If you use variables (or macro substitution) when forming SQL inquiry, availability such symbols can "break" the syntax of the query and you will get a runtime error.

Parameters SQL are designated in the inquiry by means of colon (:) before the parameter name.

For example:

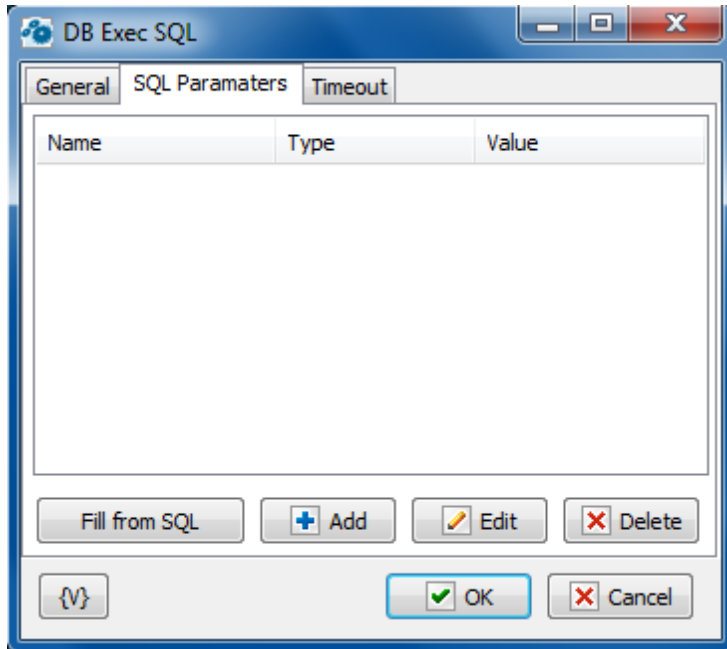

```
Select * from employee where hiredate > :dt and salary >= :amount
```

:dt and *:amount* are parameters of the query.

Parameters can be several types:

- **String** – any string

- **Integer** – an integer number
- **Float** – a real number or the number with a floating dot.
- **Boolean** – a logical value True or False.
- **DateTime** – a date and time. The value of such parameter must be defined in current system format of date and time (see the system regional settings). Pay attention that using of date-time can have its own characteristics for different databases. For example, it is better specify such parameters for the MySQL as a string parameter in the format **YYYY-MM-DD** or **YYYY-MM-DD hh:nn:ss**.

Fill from SQL

Fill the list of parameters from the current query. If a parameter is already in the list, this parameter will be without change. The function fills only the missing parameters in the list.

Add

Add a parameter manually. You will be proposed to type or select from the list the parameter name, select the parameter type and input an expression as the parameter value.

Using of variables in a parameter name and in its value is allowed. The RoboTask will substitute variable values instead of variables before performing the SQL.

Edit

Edit the properties of the selected parameter.

Delete

Delete the selected parameter from the list.

If you specify the parameter which is absent in the query, the action ignores this parameter when performing and writes the proper warning in the log of the task.

Timeout

There you can change the time of waiting of a query process. On default, timeout is 60 seconds. But in case of need, it is possible to change this parameter.

Note: *This feature is available for Business license only*

4.29.4 DB Loop

This action is similar to the [Dataset Loop](#)^[190]. The difference is that the action works within already open session.

You need to use as a query the expressions which return a set of records or strings. For instance, queries `SELECT`. DB Loop sorts out the whole set of records in a loop sequentially.

Important

You must be familiar with SQL syntax to use this action.

General

The screenshot shows the 'DB Loop' dialog box with the 'General' tab selected. The 'SQL Query' field is empty. Below it are two empty text boxes for 'Assign Field Names to Variable:' and 'Assign Field Values to Variable:'. There are two checkboxes: 'With MEMO Fields' and 'Store MEMOs as "Comma Text"', both of which are unchecked. At the bottom left is a button with a curly brace and 'V' symbol. At the bottom right are 'OK' and 'Cancel' buttons.

SQL Query

Enter the query string in SQL syntax.

Assign Field Names to Variable

Stores the field names separated by commas in a specified variable.

Assign Field Values to Variable

Stores the field values separated by commas in a specified variable.

With Memo Fields

Specifies that the query should include memo fields.

Store Memos as "Comma Text"

Indicates that the memo fields should be stored as comma delimited text.

SQL parameters

Sometimes using of parameters of a query is more convenient instead of generation of the query by means of variables. For example, when the variable value contains quotes or another special symbols. If you use variables (or macro substitution) when forming SQL inquiry, availability such symbols can "break" the syntax of the query and you will get a runtime error.

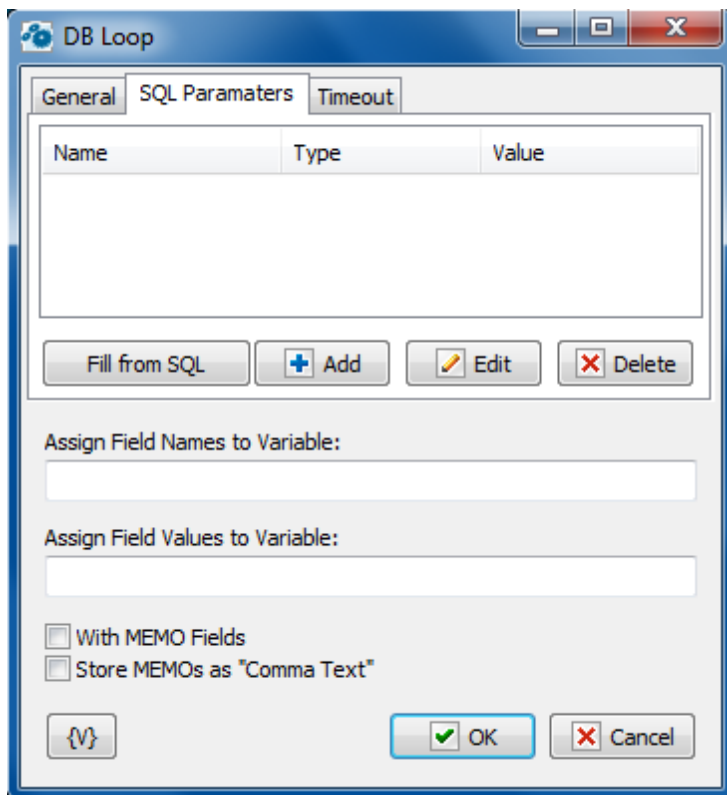

Parameters SQL are designated in the inquiry by means of colon (:) before the parameter name.

For example:

```
Select * from employee where hiredate > :dt and salary >= :amount  
:dt and :amount are parameters of the query.
```

Parameters can be several types:

- **String** – any string
- **Integer** – an integer number
- **Float** – a real number or the number with a floating dot.
- **Boolean** – a logical value True or False.
- **DateTime** – a date and time. The value of such parameter must be defined in current system format of date and time (see the system regional settings). Notice that using of date-time can have its own characteristics for different databases. For example, it is better specify such parameters for the MySQL as a string parameter in the format YYYY-MM-DD or YYYY-MM-DD hh:nn:ss.

Fill from SQL

Fill the list of parameters from the current query. If a parameter is already in the list, this parameter will be without change. The function fills only the missing parameters in the list.

Add

Add a parameter manually. You will be proposed to type or select from the list the parameter name, select the parameter type and input an expression as the parameter value.

Using of variables in a parameter name and in its value is allowed. The RoboTask will substitute variable values instead of variables before performing the SQL.

Edit

Edit the properties of the selected parameter.

Delete

Delete the selected parameter from the list.

If you specify the parameter which is absent in the query, the action ignores this parameter when performing and writes the proper warning in the log of the task.

Timeout

There you can change the time of waiting of a query process. On default, timeout is 60 seconds. But in case of need, it is possible to change this parameter.

Note: *This feature is available for Business license only*

4.29.5 DB Begin Transaction

The action begins the transaction of a database. The transaction can be finished ([DB Commit](#)^[335]) or canceled ([DB Rollback](#)^[335]). Other users cannot see any changes of database from the moment of the beginning of the transaction to the finish of it.

In case of commit, all changes of the data base from the moment of the beginning of the transaction will be written in the database and accessible to other users of the database.

In case of rollback of the transaction, all changes of the data base from the moment of the beginning of the transaction will be canceled.

The transaction acts in a current session with a data base. The action do not require any additional parameters.

Note: *This feature is available for Business license only*

4.29.6 DB Commit

The action saves all changes of a data base from the beginning of a transaction. Other users of the data base can see all the changes

The action do not require any additional parameters.

Note: *This feature is available for Business license only*

4.29.7 DB Rollback

The action cancels all changes of a data base from the beginning of a transaction.

The action do not require any additional parameters.

Note: *This feature is available for Business license only*

Part

Triggering Events

5 Triggering Events

5.1 Scheduler

Executes a task at a given time or interval. For example, you can use this triggering event to ensure your backup runs every day at midnight.

Add This Time

Enter a time to execute the action and then click the Plus button to add the time to the list.

Time List

Displays a list of times that you add with the Plus button. The Magnifier button displays the **Add Time Wizard**.

To remove a time, select a time in the **Time List** and click the Minus button. To clear the list, click the X button.

Wake the Computer to Run the task

Switch on this checkbox if you want to wake computer from "sleep" or "hibernate" mode. System timer will wake the computer 20 seconds before specified time and then the trigger will start the task.

Note:

Your system must have "Allow wake timers" enabled if you want to use this feature. This parameter is disabled by default in system installed on notebook. [See here how to enable it](#)

Time Period

Enter whether you want the action to start every day, week, or month.

Start

Select the date that you want the event starts to execute a task.

5.1.1 How to enable wake timer

1. Open Control panel
2. Open Power options
3. Click on "Change plan settings" link

Preferred plans

 Balanced (recommended)

Automatically balances performance with energy consumption on capable hardware.

[Change plan settings](#) **High performance**

Favors performance, but may use more energy.

[Change plan settings](#)

Hide additional plans

 Power saver

Saves energy by reducing your computer's performance where possible.

[Change plan settings](#)

4. Click on "Change Advanced power settings"

Change settings for the plan: High performance

Choose the sleep and display settings that you want your computer to use.

 Turn off the display:  Put the computer to sleep: [Change advanced power settings](#)[Restore default settings for this plan](#)

5. Enable "Allow wake timers" parameter for your power plan

5.2 Hot Keys

Executes a task that should be started manually. You can set up a combination of hot keys, such as CTRL + ALT + F. For example, you could set up a combination of hot keys to start Internet Explorer from your keyboard every time you want to browse the Internet.

Tip

- The **Tray Icon** triggering event also allows you start processes manually.

Hot Keys

Place your cursor in the box and press the keys you want on the keyboard. For example, press the ALT key to see "Alt" appear in the box.

5.3 Tray Icon

Executes a task when you double-click a specific icon in the system tray of the Windows Taskbar. This is useful when you want a specific action to start, such as checking e-mail.

Tip

- The **Tray Icon** triggering event also allows you start processes manually.

Icon

File Name

Enter the name and path of an .Exe or .Dll file to select an icon from. You can click the browse button to select a file.

Current Icon

Displays icons available from the file that you select in the **File Name** box.

Popup Menu Options

One can define the popup menu items for an icon on this tab. In this case the ordinal number (beginning from 1) of selected will be passed into a/the task as a parameter.

Items

The list of menu items. This list can be edited with buttons *Add*, *Edit* and *Delete*. Also it is possible to change the order of options using buttons *Move Up* and *Move Down*.

To select Default Menu Item use the button *Set Default*.

Pass Item Number as Parameter

Specify the name of parameter in which the number of menu item must to be passed. On double click on the icon, the default item number of menu will be passed.

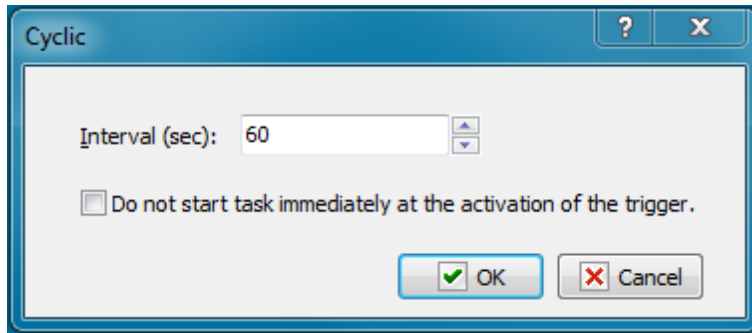

If the menu is empty, the parameter is 0 always.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

5.4 Cyclic

Executes a task at the interval in seconds that you specify. This is useful if you want to repeat a series of actions at a specific interval. For example, you can ping your web site every two minutes or check for new e-mails every five minutes.

**Interval (Sec)**

Enter the number of seconds that you want the task or actions to wait between loops.

Do not start immediately at the activation of the trigger

By default Cyclic trigger starts the task immediately when the trigger is being started. switch ON this checkbox if you want to prohibit the first running of the task. In most cases this doesn't matter, but may be helpful sometimes.

5.5 File Monitor

Executes a task when a file is created, deleted, or changed.

- [General tab](#)³⁴³
- [Save Changes tab](#)³⁴⁵
- [Pass as Parameters tab](#)³⁴⁶

General tab

Folders

Select the folders that are monitored. Each folder can be monitored with subfolders. When you click the Plus button, the **Add Folder for Watch dialog box** appears.

Include Masks (Comma Separated)

Enter one or more masks separated with commas. The wildcard mask "*.*" means that all files are being monitored.

Exclude Masks (Comma Separated)

Specify one or more masks for the kinds of files that you do not want to monitor. Separate each entry with a comma. Files that match these criteria do not appear on the result list.

Tip

You can also use wildcards in this option. Some examples of wildcards are the following:

- ***.txt** - all the files with the .txt extension.
- **mydoc?.doc** - mydoc1.doc, mydoc2.doc, mydocA.doc, and so forth.
- ***.tmp, *.\$\$\$, *.bak** - all the files with the .tmp, .\$\$\$ and .bak extensions.
- **{bakext}** - file mask(s) from the {bakext} variable.

Filter Condition

Select one or more check boxes to specify which changes in files you want to monitor:

- Watch for New Files
- Watch for Deleted Files
- Watch for Changed Files
- Time Changed
- Size Changed
- Attributes Changed

Poll Interval (Sec)

Enter the time in seconds that you want the event to wait between requests for data.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

Save Changes tab

Save Changes

Click the check box to enable the task to save changes to files during the file monitoring

session in a log.

Save in Common List

Enter the name of a log file that includes all changes during the file monitoring session. Click the browse button to select a file on the local system.

List File Name

Enter the file name of the log. Click the browse button to select a file on the local system.

Save in Different Lists

Click the check box to enable the task to save changes to file during the file monitoring session to several different logs based on the criteria you select.

Tip

- You can click a browse button next to each of the following options to select a file on the local system.

List File Name (for New Files)

Saves a log of the names of files created during the monitoring session.

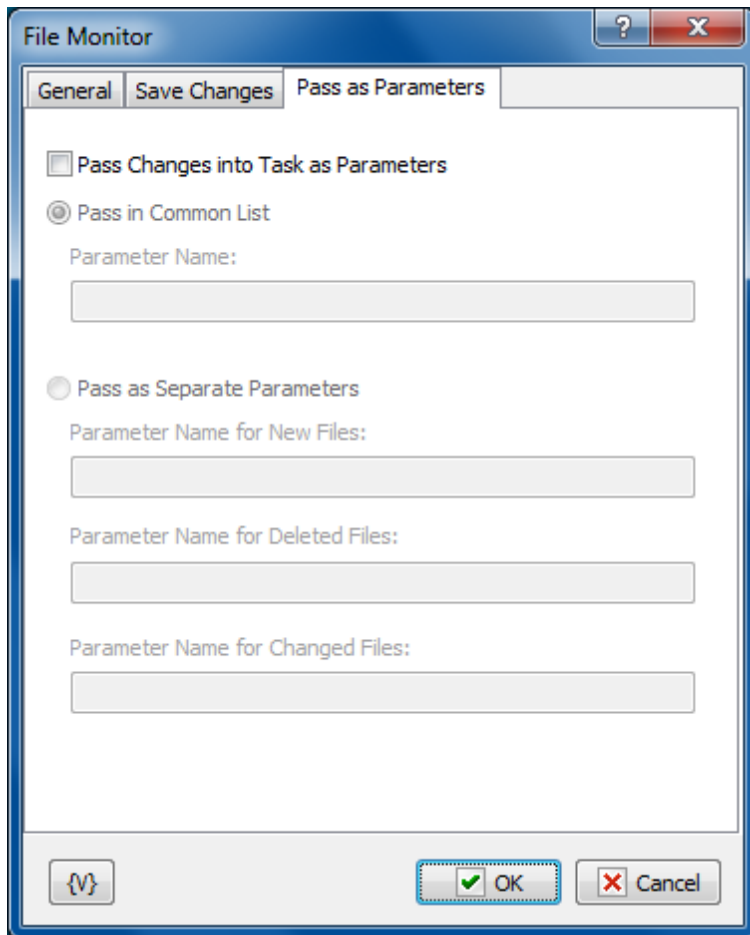

List File Name (For Deleted Files)

Saves a log of the names of files deleted during the monitoring session.

List File Name (For Changed Files)

Saves a log of the names of the files modified during the monitoring session.

Pass as parameters tab

Pass Changes into the task as parameters

Pass Common list

To pass the common list of changed, new and deleted files to the task select this option and input the parameter name for common list of files.

Parameter Name

Parameter name for common list of files

Pass as Separate parameters

Parameter Name for New Files

Parameter Name for Deleted Files

Parameter Name for Changed Files

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

5.6 Dial-Up Connection Monitor

Executes a task when the computer completes or terminates a specific dial-up connection. You can specify that RoboTask check for a connection at a specific interval; for example, you can specify that RoboTask check for a dial-up connection every 300 seconds, or every five minutes.

Dial-up Connection

Select a connection in the dropdown list. The items on the list are the names of the Internet connections for dial-up modems that you create in Windows with **Network Connections** in the **Control Panel**.

Interval (sec)

Enter the number of seconds that you want the task to wait between checks.

What to Check

Click one of the following options to tell the task to check if the connection is active or disconnected:

- **Disconnect**
- **Connect**

5.7 Expression monitor

This is a universal trigger which starts up a task in case of changing specified expression. You need to make up an expression using global variables, both systemic and user's. Expression Monitor will watch changing the value of expression after substitution of variable values. In other words, by means of the Expression Monitor, the changing of one or several variables can be controlled.

Why is the trigger universal?

You can make up your own tasks which determine a certain value by necessary algorithm using all arsenal of RoboTask. These tasks can be started up, for example, by means of trigger [Cyclic](#)^[342]. You save the received value into a global variable inside the task. Expression Monitor will start up the task in case of changing the variable.

Thereby, you can "invent" by yourself the parameter by which you need to start up a task. Expression Monitor checks the value of expression every second. So, the trigger will be activated in a second at most after changing the variable.

Expression to Monitor

Input any expression using necessary variables. Notice that only global variables can be used.

Case Sensitive

Expression Monitor is insensitive to a register By default. If it is important to take into account the register, switch on this checkbox.

5.8 Window Watcher

Runs the task when you perform some actions with windows. This task can respond to creation, destruction, activation and deactivation of a window with specified parameters. Such task can be useful if you want to introduce automatic corrective actions that respond to an error message.

General

Window Caption

Specify the window title that should be traced. You can specify a specific part of the title if it shouldn't match completely. For example:

- - Microsoft Internet Explorer
- Notepad

You can select a title from the list of windows present in the system by clicking the button to the right of the text box. When captions are compared, the case is not taken into account.

Caption must match exactly

Select this checkbox if the caption should match exactly. In this case you should specify the full window title.

Window class

Specify the window class that should be traced. You can select a window class from the list of classes present in the system by clicking the button on the right of the text box.

When strings are compared, the case is not taken into account.

Class must match exactly

Select this checkbox if the window class string should match exactly.

Advanced

**Watch hidden windows**

Select this checkbox if you want the event to trace hidden windows.

Watch child windows

Select this checkbox if you want the event to trace child windows.

Assign window handle to variable

If you want to save Window Handle for further processing in the task, specify the name of the variable. Window Handle is a unique numeric identifier of a window in the system. It can be used in the [Window Command](#)^[204] action.

Watch For

Click one of the following window states:

- **Window Activated** - the event is triggered when a new or existing window is activated. For example, a window activates when a user presses ALT+Tab on the keyboard.
- **Window Destroyed** - the event is triggered when the window is closed.
- **Window Created** - the event is triggered when a new window is created.
- **Window Deactivated** - the event is triggered when a new or existing window is deactivated. For example, a window deactivates when a user presses ALT+Tab on the keyboard.
- **Window changed caption** - the event is triggered when an existing window has changed own caption.

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

5.9 On Time Changed

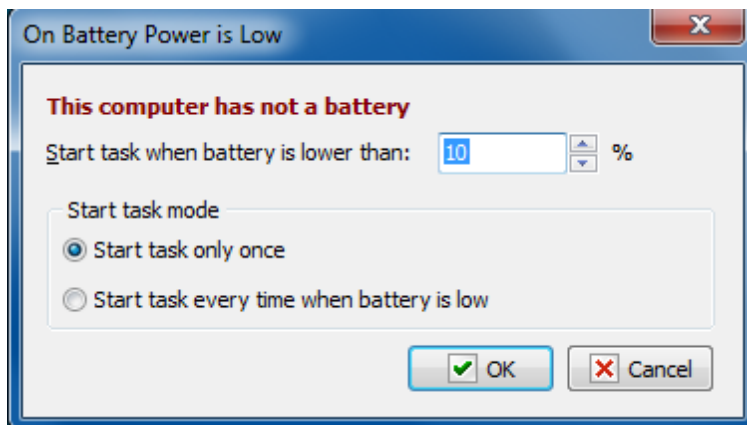

Executes a task when the computer system time changes. No specific settings are associated with this triggering event.

5.10 On Battery Power is Low

This trigger reacts to the low battery to the specified level.

Note: *this trigger makes sense only for the computers which have autonomous battery (laptop) or for computer connected to Smart UPS.*

The trigger is activated if the computer is running on battery and battery charge has dropped to the specified level. If battery charge is low but the computer is running on a network, the trigger is not activated. The parameter editor will notify you if there is not set a battery on your computer.

Start task when battery is lower than

Specify the battery level from 3% to 100%

Start task mode

- Start task only once – a task is started only once when the specified level has reached.
- Start Task every time when battery is low. – a task is started approximately one time a minute if the battery level is lower or equal to the specified one

When power supply is restored, this trigger goes to the initial waiting status.

5.11 On Spooler Changed

Executes a task when the printer spooler has changed. For example, you can use this triggering event to display a message if a particular document is sent to a printer. No specific settings are associated with this triggering event.

5.12 On Device Changed

Runs the task when a device (for example, CD or Flash Drive) is changed. The device name can be saved to a variable and used in the task.

Device Kind

Specify a type of device that triggers the task.

- All (Logical Volume & Port) - any type of device;
- Logical Volume - a logical volume mounted dynamically (CD, Flash Drive, etc.);
- Port - a COM or LPT port.

Change Kind

Specify a type of change that triggers the task.

- All (Arrival & Remove) - any type of event;
- Arrival - a device (drive) appears in the system. For example, you have inserted a new CD;
- Remove - a device is removed from the system. For example, you have pressed the eject button of the CD drive.

Assign Device Name to Variable

Switch on this checkbox and specify a name of variable where you want to save the name of the device that has been changed.

Pass Device Name into the Task as Parameter

Switch on this checkbox and specify a name of parameter which will be passed into the task at starting.

5.13 On Palette Changed

Executes a task when the display palette, or colors on the computer screen, for Windows changes. This can happen when you switch between an MS-DOS application and a Windows-based application. No specific settings are associated with this triggering event.

5.14 On Display Changed

Executes a task when the display on the computer screen changes. No specific settings are associated with this triggering event.

5.15 On Log Off

Executes a task when a user logs off or the computer shuts down. No specific settings are associated with this triggering event.

5.16 On Idle

Executes a task when the computer has been idle for a specified period of time.

**Run Job When Computer Has Been Idle for ___ Minutes**

Enter the time that you want in minutes.

5.17 On Resume

This trigger starts a task when the computer "awakes" out of the Sleep Or Hibernate mode. It does not demand any additional settings.

5.18 Listener

Allows you to start a task when a command from another computer is received. Works together with the Send Command action. Performs the primary analysis of the received string and starts the corresponding task if the received string meets the specified conditions.

Wait For Option

Select the mode of waiting for a string.

- Any string - any received string will start the task. For example, it is convenient if you exchange messages that should be just recorded to the log.
- Beginning of String - the received string should start with the key substring.
- Substring - the key substring can be in any position of the received string.
- Exact String - the received string must exactly match the key string.

Wait for String

Specify the key string that will start the task. This parameter does not make sense if the "Any String" mode is on.

Case Sensitive

Select this checkbox if strings should be compared with their letter case taken into account.

Assign Received String to Variable

Specify the name of the variable if the received string should be assigned to a variable. This value can be used in the task.

The simplest sample use is message exchange: the Listener receives a string, assigns it to a variable and starts the task. The task displays this variable as an informational message.

Plugin settings

You can set up [parameters of Network plugin](#)^[237].

Variable

Allows you to add a variable to the action or triggering event that you selected. You must place the cursor in a edit box in the settings dialog window of the action or event and then click the {V} button.

5.19 Pixels Monitor

This event starts the task when the condition of comparison of pixels on the screen or in the specified window is fulfilled. The parameter editor is very similar to the editor of the action "[Wait for Pixels](#)"^[301].

You can specify a set of pixels (one or several) in this trigger. You need to specify the necessary color and the tolerance of the comparison of pixels for every pixel.

You can specify the condition of color coincidence for a pixel set:

- Match ALL of the following pixels (AND)
- Match ANY of the following pixels (OR)

Thereby, you can specify the exactly enough condition of changes on the screen.

Source tab

When defining parameters, at first you need to specify the source of an image:

- **Window** - This is a separate window. All coordinates of pixels will be determined concerning this window. If you have selected the window as a source, you need to specify the window parameters.
- **Entire screen** - This is a screen with all visible windows.

The window parameters are similar to the parameters in the actions [Window Snapshot](#)^[292], [Window Command](#)^[204], [Window Size and Position](#)^[209], and [Window Elements loop](#)^[210].

Window Parameters Mode

There are three options:

Use Window parameters - Use the Window Caption and the Window Class to look for the necessary window.

Use Window Handle - This is a search for a window by a handle. The handle can be got in the loop Window Loop, from the trigger Wait for Window or some other way.

Use current window - This is a current window in a moment of the executing of the action. This mode does not require any additional parameters.

Use Window parameters

Window Caption.

If you want to search for a window by means of its caption, switch on this checkbox and input the expected window caption. You can input only part of the caption. In this case the action will check availability of the input part in the window caption.

Caption Must Match Exactly.

If you need the exact coincidence of a window caption, switch on this checkbox.

Window Class.

If you want to search the window by a window class, switch on this checkbox and input the expected name of the window class. You can input only part of the name. In this case the action will check availability of the input line in the name of the window class.

Class Name Must Match Exactly.

If you need the exact coincidence of a window class, switch on this checkbox. Usually it is worthwhile to search by the whole class name, because a window class is permanent and does not change its value during the "life" of the window, unlike a caption.

Select Window on the Screen.

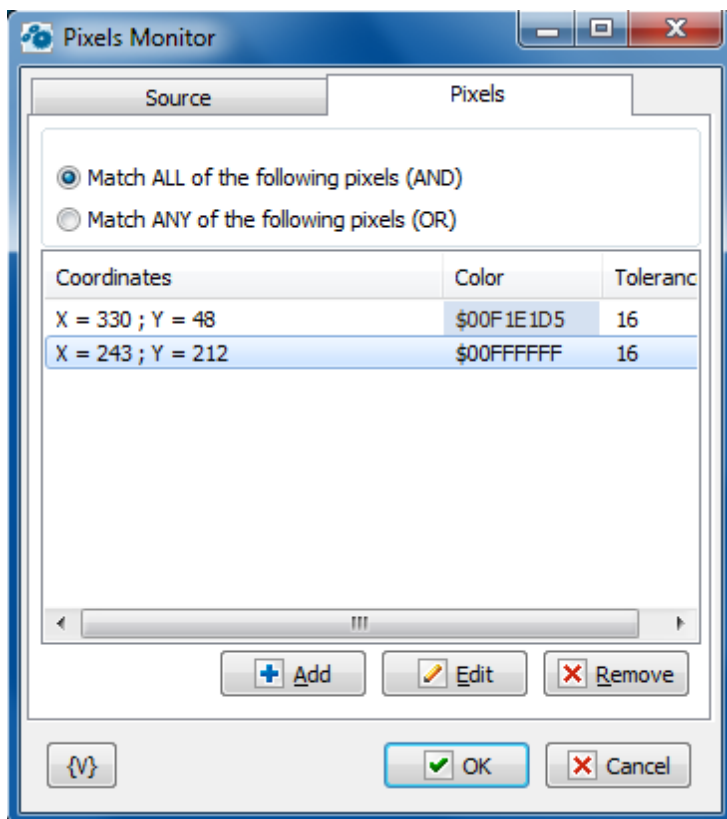

When pressing this button, you turn on the mechanism of selection a window on the screen. The window, which the mouse pointer points on, highlights with a red frame. Meanwhile, you can use the mouse to perform some actions. To select the necessary window, press *Ctrl*. To cancel - press *Esc*. When selecting a window, the fields Window Caption and Window Class are filled in automatically.

Window Handle.

Input the expression containing a window handle. This parameter is used for the mode Use Window Handle. A window handle is just a number, identifier of a window in a current session of system work.

Pixels tab

You need to specify the pixel set for checking on this tab.

Comparison mode

- Match ALL of the following pixels (AND)
- Match ANY of the following pixels (OR)

List of pixels

You can edit a list using the buttons *Add*, *Edit* and *Remove*.

By means of an edit window you can change pixel parameters both manually and by means of interactive instruments.

Pixel parameters:

X, Y - It is coordinates of a pixel from the left corner. If a source of a picture is a window, coordinates are determined from the upper left corner of the screen window.

Pattern color - This is a pattern of the color with which the action will compare the color of a pixel. Color is just a number. For comfort it is written in hexadecimal.

For example, \$0066FF00 or \$66FF00.

In hexadecimal you can write color using 6 symbols (as RGB): the first couple (younger) is red, the second couple is green, the third couple (elder) is blue color.

Tolerance - This is an accuracy of color coincidence. The error can be changed from 0 to 255 (in hex from 00 to FF). When it is 0, it is exact color coincidence. When it is 255, it is a coincidence with any color.

Tolerance is an acceptable difference between two colors for any component RGB (Red - Green - Blue). Every component of the color can ,be changed from 0 to 255 (FF in hexadecimal).

On default, the tolerance is 16.

Part

Appendix

6 Appendix

6.1 RoboTaskApp object

There is no need to create the RoboTaskApp object when you are running or editing the script. It is created before you run the script and is available as a global object inside the script.

RoboTaskApp.AddUserVariable(By Val Name as String, By Val Value as String)

Method.

Creates a user variable with the specified "*Name*" and assign the specified "*Value*" to it.

RoboTaskApp.Automation

Read-Write property, type - boolean

It is available for reading and writing. It contains the value of the RoboTask automation mode.

RoboTaskApp.Close

Method

Exits RoboTask.

RoboTaskApp.DelUserVariable(By Val Name as String)

Method.

Deletes the user variable with the specified "*Name*".

RoboTaskApp.DesktopAlert(ByVal Title as String, ByVal Msg as String, ByVal IconKind as Long, ByVal AlertKind as Long, ByVal Duration as Long, ByVal Width as Long, ByVal Height as Long, ByVal Corner as Long)

Method.

Shows desktop alert or balloon of tray icon with specified text

Title - [in] Title of the alert

Msg - [in] Message of the alert

IconKind - [in] The number of icon

0 - Information

1 - Warning (Exclamation)

2 - Error

3 - Default icon. When *IconKind* contains incorrect number the method shows default icon

AlertKind - [in] 0 - Alert window; 1 - Tray icon balloon.

Duration - [in] Duration in seconds

Width - [in] Width in pixels. If the value less that 330 the method uses default value (330).

This parameter is being ignored if *AlertKind*=1

Height - [in] Width in pixels. If the value less that 76 the method uses default value (76). This parameter is being ignored if *AlertKind*=1

Corner - [in] The corner of alert window (This parameter is being ignored if *AlertKind*=1):

0 - top-left

1 - top-right

2 - bottom-left

3 - bottom right

RoboTaskApp.EventInfoEnabled(ByVal TaskNum as Long, ByVal EventNum as Long)

Read-only property. Value type - boolean.

Returns event status (enabled or disabled) by number of the task and event number.

TaskNum - [in] task number

EventNum - [in] event number

RoboTaskApp.EventInfoEventID(ByVal TaskNum as Long, ByVal EventNum as Long)

Read-only property. Value type - String.

Returns event identifier by number of the task and event number. For example:

E_NET_LISTENER, E_WINDOW_WATCHER, E_GENERAL_CYCLIC, etc.

TaskNum - [in] task number

EventNum - [in] event number

RoboTaskApp.EventParameters(ByVal TaskNum as Long, ByVal EventNum as Long)

Read-only property, type - String.

Returns the event parameters as text. Each text line is an expression of the following type:

ParameterName = ParamaterValue

The set of parameters depends on the event type (EventID)

TaskNum - [in] task number

EventNum - [in] the event number in the task

RoboTask.EventsCount(ByVal TaskNum as Long)

Read-only property, type - Long

Returns the amount of events of the task.

TaskNum - [in] task number

RoboTaskApp.ExpandText(By Val Text as String)

Read-only property, type - String.

Expands a string containing RoboTask variables and returns the value of the string type.

For example: the string "File c:\autoexec.bat has length {FileSize(c:\autoexec.bat)} bytes" will be turned into the string "File c:\autoexec.bat has length 153 bytes"

RoboTaskApp.ExternalName(By Val ThreadID)

Read-only property, type - String.

Returns the "External Name" of a task by its *ThreadID*. You can specify an External Name on the "Advanced" tab of the task editor. You can find out the ThreadID of the current task using the *RoboTaskApp.ThreadID* property. A sample use is given below.

```
Sub Main
    Dim extName As String
    extName = RoboTaskApp.ExternalName(RoboTaskApp.ThreadID)
    MsgBox("External name is "+ extName)
End Sub
```

RoboTaskApp.Minimize

Method.

Minimizes RoboTask into the tray icon.

RoboTaskApp.Restore

Method.

Restores the RoboTask window from the tray icon.

RoboTaskApp.ServiceMode

Read-only property. It contains a Boolean value: "True" if RoboTask is running as an NT service; "False" if RoboTask is running as a regular Windows application.

RoboTaskApp.SetUserVariable(By Val Name as String, By Val Value as String)

Method

Sets the value of the "Name" user variable to the specified "Value"

RoboTaskApp.StartTask(By Val ExternalName as String, By Val TaskParameters as String)

Method

Starts the task with the specified "External Name".

TaskParameters - you can pass some parameters into started task. May be an empty string. You need write down parameters like the text, each line should be like:

ParameterName=ParameterValue

- *ParameterName* - the name of parameter, any word consisting of letters and numbers;
- *ParameterValue* - value of parameter like any set of symbols.

RoboTaskApp.StepInfoActionID(ByVal TaskNum as long, ByVal StepNum as long)

Read-only property. Value type - string.

Returns the action identifier by task number and the step number.

Returned value is an action type identifier (for example: A_TASKS_START, A_TASK_WAITCOMPETE, A_GENERAL_RUN_PROG, etc.)

TaskNum - [in] task number*StepNum* - [in] step number. Step number begins from 0.**RoboTaskApp.StepInfoName(ByVal TaskNum as long, ByVal StepNum as long)**

Read-only property. Value type - string.

Returns step status (enabled or disabled) by task number and the step number.

TaskNum - [in] task number*StepNum* - [in] step number. Step number begins from 0.**RoboTaskApp.StepInfoEnabled(ByVal TaskNum as long, ByVal StepNum as long)**

Read-only property. Value type - boolean.

Returns step name by task number and the step number.

TaskNum - [in] task number*StepNum* - [in] step number. Step number begins from 0.**RoboTaskApp.StepParameters(ByVal TaskNum as Long, ByVal StepNum as long)**

Read-only property, type - String

Returns the step parameters as text. Each text line is an expression of the following type:

ParameterName = ParamaterValue

The set of parameters depends on the action type (ActionID)

TaskNum - task number*StepNum* - step number. Step number begins from 0.**RoboTaskApp.StepsCount(ByVal TaskNum as long)**

Read-only property, type - Long

Returns the number of steps in the task by the task number

TaskNum - task number**RoboTaskApp.StopTask(By Val ExternalName as String)**

Method.

Stops the task with the specified "External Name".

RoboTaskApp.TaskCount

Method.

The read-only attribute of the numerical type. Returns the number of tasks registered in RoboTask.

RoboTaskApp.TaskEnabled(By Val ExternalName as String)

A Boolean attribute available for reading and writing. Allows you to read or set the "Enabled" parameter of the task with the specified "ExternalName".

For example:

```
RoboTaskApp.TaskEnabled("Check_email") = False
```

RoboTaskApp.TaskInfoExtname(ByVal NumTask as Long)

Read-only property, value type - string

Returns External name of the task by number of task (NumTask)

NumTask - [in] task number

Example of usage (Basic):

```
Sub Main
    Dim cnt As Long
    Dim nam As String
    Dim extNam As String
    Dim id As Long
    Dim i As Long

    cnt = RoboTaskApp.TaskCount
    RoboTaskApp.WriteToLog(1, "Total "+Str(cnt)+" tasks", RoboTaskApp.ThreadID)

    For i = 0 To cnt - 1
        extNam = RoboTaskApp.TaskInfoExtName(i)
        nam = RoboTaskApp.TaskInfoName(i)
        id = RoboTaskApp.TaskInfoID(i)
        RoboTaskApp.WriteToLog(3, extNam+"; "+nam+"; "+Str(id), RoboTaskApp.ThreadID)
    Next
End Sub
```

RoboTaskApp.TaskInfoLastStart(ByVal NumTask as Long)

Read-only property, value type - DateTime

Returns the date and the time of the last running of a task. If the task has not been running from the moment of start of the RoboTask, the result will be zero.

NumTask - [in] task number

RoboTaskApp.TaskInfoName(ByVal NumTask as Long)

Read-only property, value type - string

Returns the name of the task by number of task (NumTask)

NumTask - [in] task number

RoboTaskApp.TaskInfoID(ByVal NumTask as Long)

Read-only property, value type - long integer

Returns folder ID of the task by number of task (NumTask)

NumTask - [in] task number

RoboTaskApp.TaskInfoFolderID(ByVal NumTask as Long)

Read-only property, value type - long integer

Returns ID of the task by number of task (NumTask)

TaskNum – [in] task number

RoboTaskApp.TaskInfoState(ByVal NumTask as Long)

Read-only property, value type - long integer

Returns status of the task by number of task (NumTask)

Possible returned values are:

- 0 - (tsManual) the task has no triggering events or its triggering events are disabled (see the `RoboTaskApp.TaskEnabled` property). It waits to be run manually or from another task.
- 1 - (tsIdle) the task has some enabled triggering events. It waits to be run automatically
- 2 - (tsDisabled) the task is disabled while it is being edited.
- 3 - (tsRunning) the task has been launched and it is running.
- 4 - (tsStopping) the task received the stop command, but it is yet running. After the task is completely stopped, its status becomes either `tsManual` or `tsIdle`.

TaskNum – [in] task number

RoboTaskApp.TaskNumByExternalName(ByVal ExternalName as String)

Read-only property, value type - Long

Returns the task number by ExternalName.

You can use the `TaskInfo` method to get `ExternalName` by the task number.

ExternalName – external task name. It is any string of characters. You can specify it while editing a task (see the "External Name" parameter on the "Advanced" tab of the task editor)

RoboTaskApp.ThreadID

Read-only property, type - Long

Returns the thread ID of the task. This value is required in the `ExternalName` property and `WriteToLog` method.

RoboTaskApp.Version

A read-only property of the string type. Contains the version number of RoboTask in it.

RoboTaskApp.WHandle

A read-only property of the Long type. Contains the Handle of the main RoboTask window. This value is necessary for some Windows API functions to work properly (for example, `SendMessage`, `PostMessage`).

RoboTaskApp.WriteToLog(By Val MsgType as Integer, By Val MessageStr as String, By Val ThreadID as Long)

Method

Records a message to the task log. To record a message to the system log of RoboTask, you should set the `TreadID` to 0.

MsgType – [in] message type: 0 – regular message, 1 – warning, 2 – error, 3 - user message;

MessageStr – [in] message string

ThreadID – [in] the Thread ID of the current task. It can be obtained using the `RoboTaskApp.ThreadID` property.

If you set it to 0, the message will be recorded to the system log of RoboTask.

A sample use is given below.

```
Sub Main
  Dim thr As Long

  thr = RoboTaskApp.ThreadID
  RoboTaskApp.WriteToLog(3, "Hello World", thr)
```

End Sub

Deprecated methods

These methods are not preferred, because they are not supported by scripting languages: Javascript and VB Script.

RoboTaskApp.EventInfo(ByVal TaskNum as Long, ByVal EventNum as Long, EventID as String, Enabled as Boolean)

Method. *(deprecated method)*

Allows you to get information about the triggering event by the task number and the step number in the task

TaskNum - [in] task number

EventNum - [in] event number

EventID - [out] event type identifier (for example: E_NET_LISTENER, E_WINDOW_WATCHER, E_GENERAL_CYCLIC, etc.)

Enabled - [out] event status (enabled or disabled)

RoboTaskApp.StepInfo(ByVal TaskNum as long, ByVal StepNum as long, ActionID as String, Enabled as Boolean, Name as String)

Method. *(deprecated method)*

Allows you to get information about the step using the task number and the step number in the task

TaskNum - [in] task number

StepNum - [in] step number

ActionID - [out] action type identifier (for example: A_TASKS_START, A_TASK_WAITCOMPETE, A_GENERAL_RUN_PROG, etc.)

Enabled - [out] step status (enabled or disabled)

Name - [out] action name

RoboTaskApp.TaskInfo(By Val NumTask as Long, ExtName as String, Name as String, ID as Long)

Method. *(deprecated method)*

Sets the properties of the task with the specified number ("*NumTask*").

NumTask - [in] task number

ExtName - [out] External Name;

Name - [out] task name;

ID - [out] internal numerical identifier.

This method is used to enumerate all tasks and extract the parameter of each task. A sample use is given below.

```
Sub Main
    Dim cnt As Long
    Dim nam As String
    Dim extNam As String
    Dim id As Long
    Dim i As Long

    cnt = RoboTaskApp.TaskCount
    RoboTaskApp.WriteToLog(1, "Total "+Str(cnt)+" tasks", RoboTaskApp.ThreadID)

    For i = 0 To cnt - 1
        RoboTaskApp.TaskInfo(i, extNam, nam, id)
        RoboTaskApp.WriteToLog(3, extNam+"; "+nam+"; "+Str(id), RoboTaskApp.ThreadID)
    
```

```

Next
RoboTaskApp.WriteToLog(3,"Total " + Str(cnt) + " tasks",RoboTaskApp.ThreadID)
End Sub

```

RoboTaskApp.TaskInfo2(ByVal NumTask as Long, FolderID as Long, State as TaskState)

Method (*deprecated method*)

An additional method for getting information about the task. It allows you to get the task folder identifier and the task status by the task number.

NumTask – [in] task number

FolderID – [out] the identifier of the folder with the task.

State – [out] the task status at the moment when the method is called. It can take one of the following values:

- *tsManual* – 0, the task has no triggering events or its triggering events are disabled (see the *RoboTaskApp.TaskEnabled* property). It waits to be run manually or from another task.
- *tsIdle* – 1, the task has some enabled triggering events. It waits to be run automatically
- *tsDisabled* – 2, the task is disabled while it is being edited.
- *tsRunning* – 3, the task has been launched and it is running.
- *tsStopping* – 4, the task received the stop command, but it is yet running. After the task is completely stopped, its status becomes either *tsManual* or *tsIdle*.

6.2 Full list of system variables

Example of usage

```
{AddressOnly(John Smith <j.smith@mydomain.com>)}
{Asc(©)}
```

```
{BatteryLife}
```

```
{BatteryPower}
```

```
{CapsLockState}
```

```
{CDDiskSpace(E)}
```

```
{CDDriveCount}
```

```
{CDDriveLetter(0)}
```

```
{CDDriveModel(0)}
```

```
{CDDriveVendor(0)}
```

```
{CDMediaType(E)}
```

```
{Chr(169)}
```

```
{ClipboardContent}
```

```
{CommaSeparatedToText("item 1","item 2","item 3")}
```

```
{ComputerName}
```

```
{CurrentWindowCaption}
```

```
{CurrentWindowClass}
```

```
{CurrentWindowHandle}
```

```
{Date}
```

Description

Returns address only from full address
Returns ASCII code of specified character.

The number of seconds of battery life remaining.

The percentage of full battery charge remaining.

Checks CapsLock state

Available CD free space

CD drives count

CD drive letter by number

CD drive model

CD drive vendor

CD media type

Returns the symbol with specified ASCII code.

Clipboard content as Text

Converts commaseparated string to multiline text

Computer name

Returns the title (caption) of current active window

Returns the class name of current active window

Returns the handle of current active window

Current date

<code>{DateIncDays(- 7)}</code>	Current date ± number of days
<code>{DateTime}</code>	Current date & time
<code>{DateTimeToFormat({Date},yyyy-mm-dd)}</code>	Returns formatted date and time in specified format *
<code>{Day}</code>	Current day
<code>{DayOfTheYear({Date})}</code>	Returns the day of the year of specified or current date
<code>{DayOfWeek}</code>	Current day of week
<code>{DayOfWeekNo}</code>	Current day of week number
<code>{DefScriptDir}</code>	Default Basic script folder
<code>{DiskLoad(c:\)}</code>	Returns the disk load in percents
<code>{EnvironmentVar(Path)}</code>	Get environment variable
<code>{Eol}</code>	End of line
<code>{ExtractFileDrive(C:\Folder\File.ext)}</code>	Extracts file drive from full path
<code>{ExtractFileExt(C:\Folder\File.ext)}</code>	Extracts file extension from full path
<code>{ExtractFileName(C:\Folder\File.ext)}</code>	Extracts file name from full path
<code>{ExtractFileNameNoExt(C:\Folder\File.ext)}</code>	Extracts file name without extension
<code>{ExtractFilePath(C:\Folder\File.ext)}</code>	Extracts file path from full path
<code>{ExtractFilePathNoDrive(C:\Folder\File.ext)}</code>	Extracts file path from root folder
<code>{FileAttributes(C:\AUTOEXEC.BAT)}</code>	Returns attributes of file as string, like this: "AHRs"
<code>{FileExists({TempDir}\file.tmp)}</code>	Check file existence
<code>{FilesCount({TempDir})}</code>	Returns the amount of files in specified folder
<code>{FileSize(c:\autoexec.bat)}</code>	File size in bytes
<code>{FileTime(c:\autoexec.bat)}</code>	Returns the time of last update
<code>{FolderExists({TempDir})}</code>	Checks folder existence
<code>{FoldersCount({TempDir})}</code>	Returns the amount of folders in specified folder
<code>{FolderSize({TempDir})}</code>	Returns the total size of files in specified folder (in bytes)
<code>{FormatToDateTime(2014-02-19,yyyy-mm-dd)}</code>	Returns standard date and time from formatted string *
<code>{FreeDiskSpace(c:\)}</code>	Free disk space in bytes
<code>{GetCurrentFolder}</code>	Returns full path of current folder
<code>{Hours}</code>	Current hours
<code>{IncDays(- 1)}</code>	Current day ± number of days
<code>{IncMonths(- 1)}</code>	Current month ± number of months
<code>{IncYears(- 1)}</code>	Current year ± number of years
<code>{IPAddress({ComputerName})}</code>	Returns IP address by computer name
<code>{IsDriveWriter(0)}</code>	True if CD drive is writer
<code>{IsError}</code>	Returns "True" when error occurred at previous step
<code>{IsFileFree(c:\autoexec.bat)}</code>	Checks file for free access
<code>{IsProcessExists(notepad.exe)}</code>	Checks existence of process in memory
<code>{IsWindowActive(Notepad)}</code>	Check window existence
<code>{IsWindowHidden(Notepad)}</code>	Returns "True" if window invisible
<code>{IsWindowMaximized(Notepad)}</code>	Returns "True" if window maximized
<code>{IsWindowMinimized(Notepad)}</code>	Returns "True" if window minimized
<code>{IsWindowVisible(Notepad)}</code>	Returns "True" if window visible
<code>{LastErrorCode}</code>	Error code. Parameter of error handling task.

{LastErrorDescription}	Error description. Parameter of error handling task.
{LastErrorStep}	Error step number. Parameter of error handling task.
{LastErrorTaskExternalName}	External name of error task. Parameter of error handling task.
{LastErrorTaskID}	Error task ID. Parameter of error handling task.
{LastErrorTaskName}	Error task name. Parameter of error handling task.
{LogFileName}	Log file name (works only in context of the task)
{LogFolder}	Folder of logs
{LowerCase(Sample String)}	Converts a string to lowercase.
{Minutes}	Current minutes
{MonitorCount}	Number of Monitors
{MonthIncDays(-1)}	Current month \pm number of days
{MonthName}	Current month name
{MonthNo}	Current month number
{mSeconds}	Current milliseconds
{NumLockState}	Checks NumLock state
{OnBattery}	True - if computer on battery; False - power is online
{RandomValue(1000)}	Returns random integer value between 0 and parameter (default 1000)
{ScreenBottom(0)}	Bottom edge of specified screen
{ScreenH(0)}	Height of specified screen
{ScreenHeight(0)}	Height of specified screen
{ScreenLeft(0)}	Left edge of specified screen
{ScreenRight(0)}	Right edge of specified screen
{ScreenTop(0)}	Top edge of specified screen
{ScreenW(0)}	Width of specified screen
{ScreenWidth(0)}	Width of specified screen
{ScrollLockState}	Checks ScrollLock state
{Seconds}	Current seconds
{ShortDayOfWeek}	Current day of week short name
{ShortMonthName}	Current month short name
{ShortYear}	Two-digits current year
{ShortYearIncDays(-1)}	Two-digits current year \pm number of days
{StringLength(Sample String)}	Returns the length of specified string.
{SystemDir}	Windows system directory
{TaskCategoryID}	Category ID of current task (works only in context of the task)
{TaskExtName}	External name of current task (works only in context of the task)
{TaskFileByID({TaskID})}	Task filename by ID
{TaskFileName}	Task file name (works only in context of the task)
{TaskFolder}	Folder of tasks
{TaskID}	ID of current task (works only in context of the task)
{TaskLogFileById({TaskID})}	Task log filename by ID

{TaskName}	Name of current task (works only in context of the task)
{TempDir}	Temporary directory
{TextFile(file_name)}	Contents of text file
{TextFileANSI(file_name)}	Reads the text file as ANSI text and returns the text
{TextFileUNICODE(file_name)}	Reads the text file as UNICODE text and returns the text
{TextFileUTF8(file_name)}	Reads the text file as UTF8 text and returns the text
{TextToCommaSeparated(Line 1{EOL}Line 2)}	Converts multiline text to commaseparated string
{Time}	Current time
{TotalDiskSpace(c:\)}	Returns the total size of specified disk (in bytes)
{UniqueFileName({TempDir}*.tmp)}	Returns unique random file name by the mask
{UpperCase(Sample String)}	Converts a string to uppercase.
{UserName}	User name
{UTF8Decode(Symbols: Б, Г, БД, Бд, BS, Bs, Г)}	Decodes string from UTF8 format
{UTF8Encode(Symbols: €, £, ¼, ½, ¾, Ø)}	Encodes string to UTF8 format
{ValidFileName(c:\My<Invalid:File*Name>.txt)}	Returns valid file name
{VolumeLabel(c:\)}	Returns the label of specified volume
{WeekOfTheYear({Date})}	Returns the week of the year of specified or current date
{WinDir}	Windows directory
{WindowCaption({CurrentWindowHandle})}	Returns the title (caption) of specified window handle
{WindowClass({CurrentWindowHandle})}	Returns the class name of specified window handle
{WindowExists(Notepad)}	Check window existence
{Year}	Current year
{YearIncDays(-1)}	Current year ± number of days

(*) Format options for format variables:

d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).

ss	Displays the second with a leading zero (00-59).
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.

6.3 Command Line Parameters

Command-line options for *RoboTask.EXE*:

/ASADMIN

Start RoboTask with full rights. For operating systems with UAC (i.e. Windows Vista and later).

/REGSERVER

Register built-in COM server in your system.

/UNREGSERVER

Unregister built-in COM server from your system.

/INSTALL

Install RoboTask service

/UNINSTALL

Remove RoboTask service

/REINSTALL

Reinstall RoboTask service with default parameters.

Command-line option for *InputRegKey.EXE*:

activate <your_actual_license_key>

Silent activation if no error. Otherwise it shows the alert with error message.
